Dr. Carswell said the point he wished to make was the following: All the judges who delivered charges in the sense he had quoted agreed that uncontrollable impulse could be read into the McNaghten Rules—i.e., the rules were logically insufficient unless some such idea could be incorporated with them. The recommendation was not based upon any unproved or doubtful category of mental disorder, nor upon any principle of criminal responsibility not already recognised. His object in this communication had been to start a fresh discussion of the problem of insanity and crime from what he understood to be the point of view of the Atkin Committee, with the hope of reaching some points at which medical men could agree that the legal conception of responsibility of the insane was more in accordance with the clinical facts as they were known to psychiatrists than at present was the case.

Discussion.

Dr. **BARKER SMITH** said that people were responsible in various degrees for what they did, and that was largely proportional to their education and culture. Many men acted with the same quick, unreflective impulse as lower animals. This question of responsibility in a particular person was a question for the medical man, not for the lawyers.

Sir H. **BRYAN DONKIN** said Dr. Carswell seemed to think that the conception of irresistible impulse was implicit in the McNaghten Rules, a very strong statement to make in his, the speaker's, view. And he did not see that any practical result could arise from the view that those ideas were implicit in the rules.

Dr. G. **HENDERSON** said he did not know that the term "irresistible impulse" had ever been properly defined, yet it was due that this Association should have a definition of it. In medico-legal cases the question of responsibility constantly came up, and if this question of irresistible impulse was likely to be brought into them, the issue would be more complicated than at present. Another important kind of case was that in which a prisoner's state of mind was questioned, and sometimes the man would be sent to a criminal asylum without having been tried—i.e., without the question having been decided whether he had committed the crime or not. He suggested it would be well to try to arrive at that point in the cases in which there was a certain amount of doubt.

Dr. G. D. **MCRAE** said a very important question arising out of this discussion was, "Is an insane man a criminal, whatever he does?" To him, it was cruel to say that a man ailing mentally was guilty for anything he did, and he regarded the expression "criminal lunatic" as archaic. An individual should be tried to prove whether he committed the act, or not. If he did commit the act but was found to be insane, the verdict should be "Proven but insane," for "guilty" in this relation was out of place. The question of responsibility should be left to the legal people. It had been said that medical superintendents of mental hospitals acknowledged the principle of partial responsibility by placing patients on parole; but the actual fact was that until the patient was certified cured the responsibility for him while out on parole attached still to the medical superintendent.

Dr. T. B. **HYSLOP** said that until the medical profession awakened to the fact that in these cases it gave evidence on a question which was not at issue—namely, that of insanity, and the judge charged the jury on the question of responsibility, they would always be playing at cross purposes, and working under those absurd McNaghten Rules, which had caused grave injustice. Medical witnesses should see to it that they were examined and cross-examined on the real question at issue in the case.

Dr. W. C. **SULLIVAN** said the McNaghten Rules were really founded on a contradictory and unjustifiable view of the jury. The rules assured a degree of stupidity on the part of the jury which required that they should be instructed by the judge, and there was the further requirement that the medical evidence should be filtered through the strainer of the McNaghten Rules. The doctor giving evidence had no opportunity of expressing his views in full and in clinical terms, because the assumption was that the jury could not understand them. Yet that same jury was supposed to be gifted to the much greater degree required to distinguish between an act being irresistible and one which was unresisted. The present state of things resulted from excluding the jury from having a fair issue placed before them, hence the question was placed in the hands of the judge. It must always be borne in mind that there were very few murderers in whom something abnormal could not be found, and that abnormality could be magnified by medical witnesses to produce a verdict of "Guilty but insane"; but if the matter were left to the jury they would form their own opinion of the facts and on the history and the various episodes brought out.

Dr. J. M. **MACKENZIE** asked whether irresistible impulse was supposed to operate in persons who were sane, as well as the insane. If so, where could the line of demarcation be drawn? Much might be learned on that from Dr. Rivers's book, "Instinct and the Unconscious."

Mr. D. **CARSWELL** spoke from the legal standpoint. He agreed that some of the hard things which had been said about the McNaghten Rules were justified, but asked how medical men proposed to get rid of them, as they were operative. He therefore advocated attempts being made to arrive at a concordat with the legal profession on the matter. He knew at least three senses in which the phrase "irresistible impulse" was used by lawyers.

Dr. J. G. **SOUTAR** remarked that even after all this argument he had never yet seen a case in which he could say that irresistible impulse was the only evidence of mental disorder in a person. When such a plea was advanced, investigation showed that a definite idea had preceded the particular act, perhaps for a long time. Impulsive acts were known to occur in perfectly sane people, and in them it was well known that the acts did not indicate insanity. If the McNaghten Rules could be wiped out, members of the Association would be in a much better position as medical witnesses. The medical man had to testify to the facts, and leave it to the judge and jury to say whether the facts testified to by skilled observers were indicative of that degree of unsoundness of mind which rendered a person irresponsible for his acts.

Dr. **PERCY SMITH** said the Association had done its best to show that the McNaghten Rules should be done away with, and that every case should be tried on its merits, with the fullest possible evidence. But the profession had been saddled with the rules by the verdict of the Court of Appeal in the True case, when Lord Birkenhead said they were the law of the land.

Dr. **CARSWELL**, in a brief reply, said he recognised that the Association had remained steadfast to its attitude; that the business of the medical man was to testify to the state of mind of the accused. That was the only logically sound position.

Reviews and Notices of Books.

DISEASES OF THE CHEST.

Physical Diagnosis of Diseases of the Chest. By JOSEPH H. PRATT, A.M., M.D., and GEORGE E. BUSHNELL, Ph.D., M.D. London and Philadelphia: W. B. Saunders Company. 1925. Pp. 522. 24*s.*

THE authors divide their work into two parts. The first deals with the physical signs of the lung, the second with those of the heart. They rightly insist that the study of physical diagnosis should begin with the normal chest and proceed from that to the abnormal. Consequently they devote a special chapter to a careful survey of the localised peculiarities of the chest in health. The physics of percussion and auscultation are discussed in detail, and in general sound reasons are offered for the various phenomena observed. A full chapter is reserved for the changes due to the presence of tuberculosis. Attention is drawn to the adventitious sounds often heard in the costo-pleural sinus and to the mistake sometimes made of interpreting them as evidence of pleurisy.

The second portion of the book, devoted to a study of the physical diagnosis of the various cardiac conditions, is particularly well arranged and lucidly expressed. We would suggest that pulsation in the second right interspace is more likely to be due to retraction of the lung owing to tuberculosis than to mitral stenosis. There is a refreshing candour in the statements that "it is not easy to time murmurs accurately," and that "when instructors claim that they can do so when the heart-rate is rapid, students may comfort themselves with the knowledge that the teachers are probably mistaken and are overrating their auditory ability." On p. 371 Mackenzie *or* Burnley should, of course, read Mackenzie of Burnley.

The book can be placed with confidence in the hands of the student.

DISEASES OF THE EYE.

Swanzy's Handbook of the Diseases of the Eye and their Treatment. Thirteenth edition. Edited by LOUIS WERNER, M.B., F.R.C.S.I., Professor of Ophthalmology, University College, Dublin. London: H. K. Lewis and Co. 1925. Pp. 698. 21*s.*

THERE will always be a demand for an ophthalmic text-book neither bulky nor costly, but complete enough to satisfy the needs of the student. Twenty years ago Swanzy's text-book was deservedly reputed to be the best of its sort. To-day it has to compete with others of its size, but undoubtedly it remains one of the best. The structure of the book is substantially the same as in 1919, the date of the twelfth edition. There are some additions which add 25 pages to the book, and the whole is completely revised. The most notable alteration is that whereas in former editions diseases of the choroid were dealt with along with those of the iris and ciliary body as all belonging to the uveal tract, in the present edition choroidal diseases are classified along with retinal ones. If this is not so correct from the morphological point of view it is certainly more convenient from the clinical. In the chapter on diseases of the iris, which has been largely rewritten, we note that dental infection is hardly mentioned as a cause of inflammation of the uveal tract. Since Mr. William Lang drew attention to the subject some years ago it has come to be considered a by no means unusual cause. It would perhaps assist the student if writers of text-books were to indicate on which parts of their subject differences of opinion are legitimate. For instance, if the student is told anything at all about the pathology of retinitis pigmentosa it is only fair that he should know that different authorities hold two diametrically opposed views on it.

One of the features of this volume is the excellence of the illustrations. Of the few that have been added in the present edition perhaps the most important are the diagrams which illustrate the relations between the different parts of the visual cortex of one side and the corresponding parts of the visual fields. As we remarked in our review of the twelfth edition, the work would be improved by a short chapter on the therapeutics of the eyes including local anæsthetics. There is an unusually full appendix on the visual requirements for the public services which are not the same as when the last edition was published.

SURGERY.

Modern Surgery—General and Operative. Ninth edition. By JOHN CHALMERS DACOSTA, M.D., LL.D., F.A.C.S., Professor of Surgery, Jefferson Medical College, Philadelphia; Consulting Surgeon, Philadelphia General Hospital. London and Philadelphia: W. B. Saunders Company, Ltd. 1925. Pp. 1527. 45*s.*

THIS ninth edition has been entirely revised and reset, and though now brought up to date has been kept within the same limits. Certain chapters, previously considered desirable, have been omitted to make room for the new material; and there can be no doubt that asepsis, antisepsis, surgical bacteriology, and bandaging are best relegated to smaller handbooks. This edition was largely prepared by the author while he was on a bed of illness, and many of the chapters are the result of coöperation with his colleagues. The result is a very fine text-book of surgery, which evidently has an established reputation in the United States. One of its most striking features are the chapters at the end of the book on X rays, radium, and electrothermic methods of treatment. They give a detailed account of the uses of these various aids to the surgeon and provide useful notes for reference by practitioners and students. The book is freely illustrated and well got up.

Text-book of Orthopedic Surgery for Students of Medicine. By JAMES WARREN SEVER, M.D., Boston, Massachusetts, Assistant Orthopedic Surgeon, Children's Hospital, Boston; Instructor in Orthopedic Surgery, Harvard Medical School. New York: The Macmillan Company. 1925. Pp. 353. 20*s.*

As its title suggests, this is a rather elementary work, suitable as an introduction to the subject for students of medicine and as a survey of the scope of the specialty for nurses and even for educated laymen. Dr. Sever, in his preface, claims with justice that the book is written in simple terms, and that the student will not be led astray if he follows the advice here given. If, however, information is wanted as to the details of treatment or the technique of an operation it is to a more advanced and pretentious work that the inquirer must turn. For instance, although the author discusses the treatment of congenital dislocation of the hip and the necessary retentive appliances, he gives no hint as to the manipulations which may be necessary for the reduction of the luxation. Some other subjects are dealt with in similar fashion, while tuberculosis of bones and joints receives a good deal of attention. Even here the treatment of Pott's disease (the author has knighted the great Percivall) by the Albee and Hibbs methods is dismissed in a dozen lines of large print, and we have found no allusion to other operative procedures which have been advocated in caries of the spine. Hip disease and its treatment, especially that with the Bradford splint, and tuberculosis of the knee, ankle, and foot are dealt with from a properly conservative point of view. The author's remarks as to the importance of free removal of the diseased bone, if any cutting operation becomes necessary, are to be commended, and we endorse his conclusion that in tuberculosis of the ankle affecting adults the method of choice is generally amputation. The surgery of obstetrical paralysis of the shoulder is dealt with at some length and operations for its relief described, but the references to the operative treatment of other paralyses are sketchy and inadequate. The preparation and fitting of splints and supports are well described, and the technique of plaster-of-Paris is as thorough as would be expected from a member of the Boston School of Orthopædics.

POST-MORTEM APPEARANCES.

By JOAN ROSS, M.B., B.S. Lond., M.R.C.S., L.R.C.P., Assistant Pathologist to St. Mary's Hospital, London. With Preface by E. H. KETTLE, M.D., Professor of Pathology, Welsh National School of Medicine, Cardiff. London: Humphrey Milford, Oxford University Press. 1925. Pp. 216. 7*s.* 6*d.*

THIS well-printed little book sets forth in as compact a form as possible the characteristic post-mortem appearances encountered after death from various causes. The introductory remarks include a brief account of the method of performing a post-mortem examination and of the methods for preserving specimens for museum purposes. Section 1 describes the appearances seen after death from various physical and chemical agents; this is followed by sections dealing with the various diseases, general and systemic. There is a useful appendix giving, among other things, tables of average normal weights and measurements of organs.

The typical post-mortem findings in various types of disease are described in a brief and practical manner, and the book will be found most useful both to the student and to those who may be called upon to perform an occasional post-mortem examination.

DISEASES OF CHILDREN.

Twelfth edition. By the late Sir JAMES F. GOODHART, Bt., F.R.C.P. Edited by G. F. STILL, M.D., F.R.C.P., Physician, King's College Hospital, and Hospital for Sick Children, Great Ormond-street. London: J. and A. Churchill. 1925. Pp. 966. 28*s.*

THERE can be few medical readers who are not familiar with this well-known work, which has now been a standard text-book for 40 years. Dr. Still has carried out with notable success his object of bringing the book up to date without unnecessary alteration of its form. This twelfth edition contains four new chapters; encephalitis and erythrœdema are included for the first time, and separate chapters are devoted to diabetes and the purpuras. A number of minor additions have been made throughout the book. The popularity of "Goodhart and Still" among students and practitioners will be maintained by the new edition.

ANATOMY.

Hand-Atlas of Clinical Anatomy. By A. C. EYCLESHYMER, B.S., Ph.D., M.D., and TOM JONES, B.F.A. London: Henry Kimpton. 1925. Pp. 424. 50*s.*

THIS atlas is a further growth and development of the "Manual of Surgical Anatomy" which was prepared for the use of the American Medical Services during the late war. Female anatomy has been included, and a certain amount of rearrangement and introduction of new plates has taken place. There is no doubt that the work, especially in its original form, met with a very good reception and demand in the country of its birth; equally without doubt it would be of considerable value to anyone called upon to carry out some surgical work, but possessing little experience to direct him and no anatomical memory as a guide. We confess, however, that we feel some disappointment with the book. It is little more than a collection, necessarily incomplete, of plates of gross anatomy. Such anatomy should be unnecessary for the operating surgeon, although it is conceivable that he might be glad of some anatomical advice in out-of-the-way circumstances. There are many points of surgical interest which could usefully find a place in an anatomical work for which we have looked here in vain—for example, the varieties in the cystic artery, or the palmar relations which are so fundamental in Kanavel's work on infections of the hand. A figure is certainly given from Kanavel, but no attention is paid to the areolar palmar spaces and their relations, and in the scheme of incisions on p. 274 the value of the lines shown would be vastly increased if there were some references or an explanatory diagram similar to those in the figure on p. 128. As in most books with many figures, some slips have missed the eye of the proof reader; we cannot help feeling doubt, too, about the nerve to which attention is called on p. 125. The figures are clear and good, and those showing usual incisions are among the best we have seen. A full and good explanatory index ends the volume, which is well produced and printed.

A Short History of Anatomy. By RICHARD H. HUNTER, M.D., Lecturer in Anatomy, Queen's University, Belfast. London: John Bale, Sons and Danielsson. 1925. Pp. 51. 2*s.*

THE time of a student of to-day is so taken up with things that have to be done that it would be cruel to suggest the further task of historical research, but this booklet, containing a quantum of reliable information, can be read through in a very short time, and will give the reader an idea of when some of these masters of ancient medicine had their being and of some of the things they did. Only those who love these dim, old, half-forgotten figures will try to get on better terms with them, but all ought to understand that medicine and its relations are not growths of yesterday and to-day, but that their roots were planted in very remote soils, and that their upgrowth was fostered in the past by many great and learned men. We would like to see brochures like this one in the hands of all students of medicine.

SYMPATHETIC DISORDER.

Vagotonies, Sympathicotonies, Neurotonies. Les états de désequilibre du système nerveux organo-végétatif. By A. C. GUILLAUME. Paris: Masson et Cie. 1925. Pp. 281. Fr.14.

THE output of books dealing with the sympathetic nervous system has been on the increase during the last ten years, in particular since the clinician began to apply to his own studies the conclusions drawn from experimental and pharmacological researches by the physiologist. These volumes, as must be admitted by those who have had occasion to read and test them, have been of rather pronounced inequality in merit, for not a few have been characterised by superficiality and too many by the tendency to simplify the subject by ignoring its complexities; still another fault is the habit of interpreting obscure phenomena by reference to mechanisms which have themselves scarcely emerged from obscurity.

On perusal of Dr. Guillaume's handy volume we think we may say these imperfections are less in evidence than usual in books dealing with its topic. The author takes the well-known dicta of Eppinger and Hess as to the differentiation between the two clinical types of vagotonus and sympathicotonus, and after an independent study of his own comes to the conclusion that mixed types are more common than either of these, and stresses the importance of recognising, as is too often forgotten, that the phenomena attributable to sympathetic disorder which the clinician encounters are occurring in an intact organism and not in organs which have been isolated as in most physiological and pharmacological experiments. His book really serves as a kind of introduction to the subject, and it is one which we consider will repay close examination, for the author is temperate in his assertions and cautious in his conclusions.

NEUROLOGICAL DIAGNOSIS.

Kompendium der topischen Gehirn- und Rückenmarksdiagnostik. Sixth revised and enlarged edition. By ROBERT BING, Professor in the University of Berne. Berlin and Vienna: Urban and Schwarzenberg. 1925. With 102 illustrations. Pp. 242. M.9.90.

WE have on several occasions given hearty recommendation to this now well-known and appreciated compendium of neurological diagnosis. It has appeared, we are informed, in Spanish, Russian, Polish, French, and Hungarian editions, as well as in English. Its commendable features are its relative uncomplexity, its clarity of exposition, the absence of controversial matter, and the conspicuously useful and simple diagrams scattered liberally through its pages. Learning is thus rendered as easy as possible by every device known to the teaching expert. On previous occasions we have found statements open to criticism and in need of correction, and it is satisfactory to note that some at least of these have been altered; in particular, it is now stated (p. 201) that certain involuntary movements are not caused by "irritation" but are of the nature of release phenomena. On the other hand, we consider the statement (p. 228, footnote) that spasmodic laughing and crying may be caused by the "irritation" of lesions in the vicinity of the thalamic reflex centres unfortunate and in need of modification.

L'Innervation périphérique. By Dr. EMILE VILLIGER, Professor in the University of Bâle. French translation by Dr. PIERRE HOFF, Chef des travaux anatomiques at the University of Geneva. Paris: E. Le François. 1925. With 66 illustrations. Pp. 214. Fr.22.

FOR the student of nervous anatomy a book such as that of Prof. Villiger is certain to prove useful and practical, though its title rather belies its contents. Not only is the peripheral nervous system in the strict sense fully described, but there are also sections dealing with nerve roots and their distribution, muscles and their innervation and actions, the sympathetic nervous system, and the central connexions of both motor and sensory nerves; the author has also managed to incorporate a few paragraphs on the clinical aspect of lesions of the motor and sensory tracts. The French translation reads easily and clearly.

PHYSIOLOGY OF REPRODUCTION.

Reproduction in the Rabbit. By JOHN HAMMOND. Edinburgh: Oliver and Boyd. 1925. With 20 plates and 40 tables. Pp. 210. 15*s.*

ANIMALS multiply in a variety of ways—sexually, by parthenogenesis, polyembryony, or budding. Even more diverse in detail are the breeding methods of different mammals. Reproduction is, indeed, one of the best illustrations of the great truth that the constants—i.e., the laws—of biology are the ends rather than the means, the results rather than the mechanisms by which they are achieved. Our knowledge of the physiology of œstrus, ovulation, conception, pregnancy and the rest seems much less advanced than it ought to be, and this delay is to a large extent due to attempts to generalise from one or two examples. This is now obviously impossible and the facts have to be worked out for each species separately. Mr. Hammond has here put together the data he has accumulated during several years' work at the School of Agriculture at Cambridge, and Dr. F. H. A. Marshall contributes an introduction and a chapter on the formation of the corpus luteum. The result is an interesting and well-documented work in which the processes in the rabbit are described and compared with those known in other animals. It will also be technically useful to those engaged in breeding rabbits. Unfortunately, the illustrations are with few exceptions poor.

POPULAR HYGIENE.

The Fight against Infection. By G. E. F. STAMMERS, Lieut.-Colonel R.A.M.C. (ret.). London: Faber and Gwyer. 1925. With 24 text figures. Pp. 214. 2*s.* 6*d.*

NEVER were the general public so anxious to be healthy as they are now, and this excellent little book will help them to understand what infection by parasites is and how it may be dealt with. After a general account of germs and resistance, Colonel Stammers takes ankylostomiasis, malaria, plague, sleeping-sickness, and enteric diseases as more detailed examples, and interpolates an admirable discourse on the text that scientific discovery is a process and not an event. It is, we think, rather a mistake to describe so many diseases with which we are now quite unfamiliar. The temptation which the spectacular successes of tropical hygiene offers is difficult to resist, but it is apt to give some impression of unreality; the quieter triumphs of domestic health work are in the end, perhaps, more convincing. It is, of course, difficult to say exactly how infantile mortality has been reduced to about one half of what it used to be, but the lay public would appreciate from this homely example that the fight against infection is one in which everyone can take part in quite a real daily way.

A TEXT-BOOK OF GENERAL BACTERIOLOGY.

Eighth edition. By EDWIN O. JORDAN, Ph.D., Professor of Bacteriology in the University of Chicago and in Rush Medical College. London and Philadelphia: W. B. Saunders Company. 1925. Pp. 752. 25*s.*

THE eighth edition of this text-book has still left it of manageable size and pleasing appearance. The section upon anaerobes has been revised and the book brought up to date by the inclusion of recent work upon the bacteriophage, scarlet fever, tularæmia, &c. There is little to add to the praise given to the book in the reviews of former editions. It maintains its position as one of the best balanced and most scholarly of the current text-books upon bacteriology and has the additional charm of viewing the subject widely, not being slavishly devoted to the pathogenic micro-organisms to the exclusion of due consideration of other forms.

JOURNALS.

JOURNAL OF INDUSTRIAL HYGIENE.—In the issue for October a contrast is drawn by D. R. Wilson, after a visit to America, between the way in which investigations into industrial activity are being conducted in that country and at home. Much work is being done in both places, but in America there is less coördination of research, rather more laboratory experiments, and rather less observations under industrial conditions. On the other hand, coöperation between engineers, technicians, physiologists, and psychologists is closer in America, and employers and operatives combine more to support inquiries of common benefit to both. Persons interested in experiments with animals on dust inhalation will find a useful note by C. K. Drinker, P. Drinker, and K. R. Drinker. These workers point out that by adding 10 per cent. carbon dioxide dusty atmospheres breathing is increased, anp comparatively short exposures result in a uniform and satisfactory distribution of dust particles in the pulmonary alveoli. By this means periods of exposure can be usefully shortened.—The chief article deals with the manufacture and repair of electric accumulators; it is contributed by C. W. Price and J. C. Bridge, two Home Office inspectors, who present the results of an intensive investigation of the industry in Great Britain. The industry, owing to demands for motor-cars and for wireless apparatus, has improved of late, with a great increase in cases of lead poisoning. They show how close is the incidence of cases to efficient exhaust ventilation for carrying away dust and fumes. For this purpose the various processes of casting the lead plates, of pasting them, of trimming and assembling them is described. The workroom conditions in which these processes are carried out are dealt with in detail, and recommendations are made for improving these conditions and so minimising the risk of lead poisoning and improving the general health of the workers. Arrangements for medical examination and accommodation for personal hygiene are considered. The result of this report led to the establishment of a new code of regulations, which came into force this year. The way in which this code strengthens the various safeguards is pointed out. This article is one of considerable importance.——November, 1925: A comparison of past diseases in university students coming from rural and urban districts is presented by W. P. Shepard and H. S. Diehl. Data were collected from 3478 males and about 1500 females. The common diseases in order of frequency were: measles, mumps, chicken-pox, whooping-cough, influenza, tonsillitis, scarlet fever, pneumonia, small-pox, and diphtheria. Students from rural communities were highest in past histories of pleurisy, pneumonia, rheumatism, small-pox, and tuberculosis; and lowest in chicken-pox, diphtheria, tonsillitis, typhoid fever, and whooping-cough. In contrast students from large cities were highest for chorea, and lowest for appendicitis, influenza, measles, mumps, pleurisy, and small-pox. The totals did not rise or fall regularly according to density of population. The areas were grouped into rural, villages, towns, small cities, and large cities, in order of population density. The totals for past history of infectious diseases came out: villages 317, small cities 296, towns 252, rural 232, and large cities 231. The present position of factory legislation in Australia is stated by D. G. Robertson. Each State in the Commonwealth has wide legislative powers and functions. Hence there is no one code prevailing throughout. The State of Victoria was the first to adopt legislation, which has been progressive and modelled upon the legislation of Great Britain. New South Wales, although an industrial State, followed later and has not progressed so far. Other States have legislation, but it is not extensive. There is need to-day for improvement and for the wider adoption of a uniform code. Action on these lines was taken at an industrial hygiene conference held in 1922, at which Dr. A. J. Lanza was present. Certain resolutions were then adopted as recommendations for consideration by the several States; these resolutions are given in detail. Since this conference, legislative advance has been made in Victoria and New South Wales, where medical inspectors of industrial hygiene have been appointed, and further powers to call for periodical medical examination have been taken in Western Australia.—The most important paper is one by M. S. Iszard, who recounts an investigation into the effect of calcium when inspired as a dust upon tuberculosis. Calcium hydrate was found not to be harmful to the lungs of rabbits, and to stimulate migration of macrophages containing silica particles. Inoculation with tubercle bacilli after a period of dust inhalation showed slight retardation in the development of tuberculous lesions. When lime dusting occurred after inoculation the retardation was more distinct. The investigation upon which these conclusions are based are carefully described and represent an extensive piece of useful, although somewhat negative, research.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the health statistics for 1924 of a group chiefly composed of counties and combined districts:—

Name of district.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Cambridgeshire (excluding Cambridge) ..	70,950	15·9	12·9	0·90	1·89	2·2	—	52	2·7
Cambridge B. ..	59,120	14·1	11·8	1·04	1·42	2·1	21	55	7·2
Heston and Isleworth U.D. ..	46,970	17·7	10·8	1·04	1·34	2·0	27	60	1·2
W. Gloucestershire C.D. ..	48,862	18·4	11·2	0·51	1·53	2·1	30	62	—
Herefordshire C.D.	50,371	18·7	13·6	0·76	1·67	2·6	24	52	3·2
Dumfries* ..	44,530	22·2	14·3	1·07	1·55	2·3	—	74	9·1
Isle of Ely ..	76,070	18·7	11·5	0·68	1·56	1·8	34	59	4·9
Stirling*	78,270	23·7	13·2	0·89	1·19	2·7	31	74	7·0

* Statistics of landward areas of county. B. = Borough.
C.D. = Combined district. U.D. = Urban district.
— = Figures not available.

Cambridgeshire.

Dr. Frank Robinson reports progress in the scheme for the provision of nurse-midwives in all the rural parishes of the county. The county council does not subsidise midwives directly but makes grants for the training and maintenance of midwives who will also act as sick nurses in the employment of the District Nursing Association and as infant life protection visitors for the Poor-law guardians. Of the 50 midwives now practising in the county only three are untrained, and of the 129 rural parishes there remain only 28 for which nurse-midwives have not been provided. Progress has also been made in the provision of pure water. In the Newmarket Rural District 103 water samples were analysed and 83 were found to be polluted; and in one parish out of 100 houses supplied by polluted wells 55 have been connected with the public water main. In other districts new wells have been sunk.

Cambridge.

Dr. Andrew J. Laird points out that the maternal mortality in Cambridge for the years 1919–22 was 2·39, as compared with 4·11 for England and Wales. Little use has been made so far of the arrangements for antenatal supervision, and Dr. Alice L. Robson suggests that the confidence of doctors and midwives can best be secured by the appointment of a specialist for this work. There is an arrangement for sending special antenatal cases to the out-patient department of Addenbrooke's Hospital; a fee of 10*s.* 6*d.* is charged for consultation and report and 2*s.* 6*d.* for each subsequent attendance. Arrangements have also been made with the same hospital for the admission of difficult cases of labour, normal confinement cases where the home conditions are prejudicial, and children under 5 suffering from ophthalmia neonatorum, epidemic diarrhœa, and non-infectious ailments. The charges made are 7*s.* per day for each adult (in addition to the surgeon's fee according to the scale under the Midwives Act), and 5*s.* per day for each child. Mr. W. B. Grandison, the public dental officer, reports on the dental scheme for mothers and pre-school children. When a baby has cut four teeth it is enrolled in the scheme and the mother promises to bring it to the clinic at least every six months thereafter. If this arrangement were carried out, says Mr. Grandison, every child should enter school free from dental disease, but unhappily there are lapses from grace. During 1924 67 mothers were recommended for dental treatment and 47 availed themselves of it. "Dental work for expectant and nursing mothers is almost confined to the complete elimination of teeth and their replacement by artificial substitutes." The exceptions are those mothers who previously attended the school dental clinic. During 1924 150 houses were erected, all with State assistance; 68 of them were put up by the local authority and 82 by other persons. There are at present 1324 applicants for corporation houses and many of these have been waiting for years.

Heston and Isleworth Urban District.

Dr. Elwin H. Nash reports that at the end of the year there were 51 private wells in use for water-supply and that in nine of these an alternative supply existed for domestic purposes. In 63 instances taps were placed on the main in compliance with a notice from the health department, in substitution for taps on pipes connected with inaccessible and uncovered cisterns. This remedies a very common source of pollution of the pure water from the main. A small outbreak of mild small-pox is recorded, in which seven secondary cases were infected by a tramp. Dr. Nash describes recurrent outbreaks of diphtheria during 1923–24 in a residential school dealing mainly with Poor-law boys. At the end of 1924 the whole school was Schick-tested and the non-immunes immunised. Of the 50 members of the staff, 15 were Schick-positive. Of the 489 boys 63 were positive. Two of the nurses when immunised had severe reactions, and the third had a very bad arm and was ill for six weeks. In the opinion of Dr. R. A. O'Brien, of the Wellcome Laboratories, the symptoms in the nurses were due to protein sensitiveness. None of the children showed the slightest inconvenience. There were 33 notifications of encephalitis lethargica, which occurred in two small outbreaks in a small and populous area of Hounslow. The housing conditions in the district remain unsatisfactory. In his school report Dr. Nash draws attention to the large amount of futile work involved in treating ear discharges and would like to see ionisation made available in the district. He is also opposed to the routine removal of enlarged tonsils, as he finds that many disappear after a septic mouth has been cleaned up. Complete enucleation is, he considers, the only proper method.

West Gloucestershire (United District).

Surgeon-Captain O. W. Andrews reports that progress has been made in the building of new houses, and mentions that many people object to being obliged to supply fixed baths which they say may be used as potato stores. The small-pox epidemic in the East Dean district began in April, 1923, and the last case was notified in May, 1924. Of the other districts in the combination Gloucester Rural was the only one affected by small-pox. Altogether there were 311 cases in East Dean with two deaths, and 24 cases in Gloucester Rural with no deaths. Dr. G. F. Rigden finds that there is a slow awakening of the public to the importance of antenatal work, but that "we are still far from the day of routine antenatal examination."

Herefordshire Combined District.

Dr. Herbert Jones states that one-fourth of the cottage houses have a distant water-supply, making a proper standard of cleanliness difficult. It is a constant practice to complete the building of a cottage before ascertaining whether there is a suitable water-supply available. The duty thrown on the rural district councils of enforcing a proper water-supply is not satisfactorily carried out. Of 80 samples of water examined, 32 were reported unfit. In many parts of the district "dip" wells are the source of supply. These are readily polluted, but when they are situated on a slope they can easily be made safe by enclosing them and providing a pipe outlet to slightly lower ground. The slop drains from many cottages discharge into the roadside ditch, and this practice has even been permitted in newly erected houses. The routine inspection of houses was discontinued in 1914 and is still in abeyance owing to the increased cost of executing repairs. Dr. Jones considers that it should be resumed. He discusses the difficulty of providing water-supply and drainage in rural districts, and expresses the opinion that financial assistance from the State should be forthcoming towards the provision of rural water-supplies and sewage disposal works. Between 10,000 and 12,000 men, women, and children come into the combined district for about four weeks in August and September for the hop-picking. Their employers pay much greater regard to the welfare of pickers than formerly. The Bromyard and Ledbury Councils, however, have not yet adopted the by-laws drawn up for the accommodation of hop-pickers in other districts.

Dumfries.

Dr. J. Maxwell Ross states that the increase of occupied houses is due partly to building but also to reoccupation of empty houses. In the village of Kirkconnel there are 21 one-roomed houses still used, six of which are occupied by three persons, five by four persons, one by five, and four by six. The analysis of the samples of Esk water supplied to Gretna and Eastriggs showed that the chemical treatment adopted, though expensive, was effective. The need for using the Esk water ceased in November when the gravitation supply became available. The River Nitt has been surveyed from its rise in Ayrshire to its fall into the Solway, and a good deal of pollution was found in Dumfries-shire owing to coal-washing and various sewage effluents. At one school an arrangement was found by which water from a mill stream was diverted to a channel under the seat of the latrine, the fæcal matter being washed out through a pipe on to the banks of the stream. This is reminiscent of the methods adopted by the monks at Kirkstall Abbey and other monasteries. There is practically no industrial pollution of the River Annan, and the sewage effluents of Moffat and Lockerbie are fairly purified before they reach the main stream.

Isle of Ely.

Dr. J. Pixton Walker reports that the death-rate in illegitimate infants has gone down from 120 to 80, and goes on to state that "a detailed examination of dates of birth of first-born children has shown us whole villages where forced marriages must have been the rule rather than the exception." About 60 samples of milk are examined annually under the Food and Drugs Acts, and the analyst's report has shown curious results during the last three years. The average fat-content in 1922, 1923, and 1924 was 3·58 per cent., 3·65 per cent., and 3·78 per cent. respectively, whilst the average non-fatty solids for the same years was 8·74 per cent., 8·72 per cent., and 8·56 per cent. The county council does not subsidise the Isle of Ely County Nursing Association, which will "probably soon be disbanded for lack of interest and of funds." A handsome nurses' home, however, with a maternity ward, has been erected for the March District Nursing Association, and the chairman of the county council at the opening proceedings stated that the county council pay £3 per annum towards administration expenses for every nurse employed by nursing associations who performs duties for the county council.

Stirling.

Dr. T. Adam reports that the new coördinated scheme of medical and nursing services which has been in operation since the beginning of 1924 has worked very smoothly and has given every satisfaction. Consideration is given to the suggestion of the Board of Health that fever nurses should spend two years in training at a fever hospital and subsequently two years in a general hospital so as to qualify, after examination, for both the fever register and the general register. It is pointed out that for the purpose a unit area is needed which includes both types of hospital. The central district of the county forms such an area readily, and the probationer staff of the two fever hospitals could easily pass on to the Stirling Royal Infirmary to complete their training after two years at the fever hospitals. Dr. Adam cordially approves of the new proposals. No antenatal clinics have so far been established in the county. The pollution of the rivers of the county by paper mills is receiving considerable attention.

Dumbarton.

Dr. Thomas Lauder Thomson reports a considerable outbreak of scarlet fever in the western district with which the Dumbarton Joint Hospital was inadequate to cope. There were 515 cases notified, several of which were of a severe type, and there were nine deaths. In two cases the infection spread to dairy farms, but it did not appear that the epidemic was to any appreciable extent milk-borne. Dr. Thomson thinks that the curtailment of the supply of milk to expectant and nursing mothers has caused hardship, especially in districts where there is much unemployment. There is no maternity hospital in the county. Of the 22 midwives practising, 16 have only the "bona-fide" qualification. The institutional accommodation for the treatment of tuberculosis is unsatisfactory. The county council have no control of the institutions used, patients frequently have to wait a long time for admission, and it is almost impossible to find accommodation for non-pulmonary cases. Dr. Thomson advocates the provision of a tuberculosis institution by the committees of the eastern and western districts, either by themselves or jointly with other authorities. The beds required for Dumbarton would be about 30 for pulmonary cases and 15 for non-pulmonary cases. Several improvements in the tuberculosis scheme have been approved, but the question of the provision of the sanatorium, of more dispensaries, and of a bacteriological laboratory is to be further considered.

South-West Kent United Health Area.

Dr. S. Nicol Galbraith reports that the arrangements for the hop-pickers in Kent leave much to be desired. The bad weather of 1924 showed up the unsatisfactory nature of their dwellings. "The sanitation in some camps was deplorable; in some positively indecent." He recommends the appointment of a permanent inspector. Temporary inspectors have done some good, but the time to get defects put right is not during the hop-picking, but between the seasons. In addition to the danger from infections amongst the pickers, other diseases such as rheumatism, pneumonia, and bronchitis have to be considered. Twenty-two deaths were registered among the families of the pickers, including those of 17 children, nine of whom were under 1 year of age. The hoppers' dwellings at East Farleigh come in for special condemnation. As a contrast to the bad conditions, some farmers provide model dwellings and offer prizes to the pickers for the best kept homes. It is suggested that the temporary hut encampment used for soldiers at home and abroad during the war should be taken as the minimum standard. The hop-picking in Kent means the migration of about 60,000 people into South-West Kent, and it is obvious that their accommodation is a problem which demands very careful consideration both from the point of view of the health of the pickers and of the menace to the health of the permanent residents.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 21st, 1925.

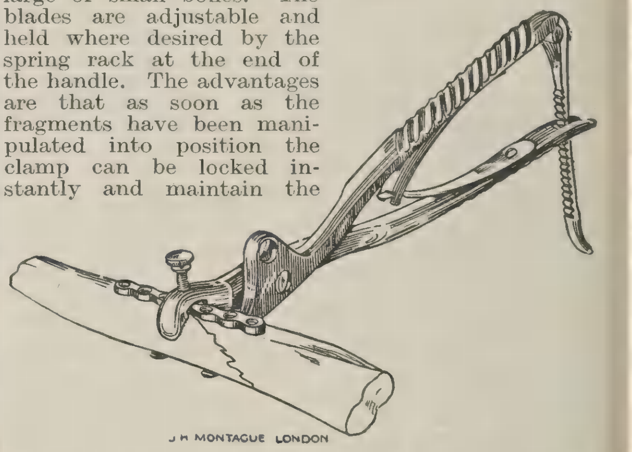
Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 68; scarlet fever, 2464; diphtheria, 1031; enteric fever, 44; pneumonia, 1186 (as compared with 889 in the previous week); puerperal fever, 53; cerebro-spinal fever, 8; acute poliomyelitis, 11; encephalitis lethargica, 30; continued fever, 1; dysentery, 7; ophthalmia neonatorum, 98. There were no cases of cholera, plague, or typhus notified during the week.

Deaths.—In the aggregate of great towns, including London, there were 3 deaths from enteric fever (none in London), 49 from measles, 13 from scarlet fever, 30 from whooping-cough, 29 from diphtheria, and 61 from influenza. In London itself there were 8 deaths from diphtheria and 24 deaths of infants under 2 years of age from diarrhœa and enteritis.

New Inventions.

COMBINED BONE AND PLATE HOLDING FORCEPS.

I have had in use for nearly two years a combined bone and plate holding forceps, which has given every satisfaction. It consists of two blades made on the principle of the well-known Peters forceps for large or small bones. The blades are adjustable and held where desired by the spring rack at the end of the handle. The advantages are that as soon as the fragments have been manipulated into position the clamp can be locked instantly and maintain the correct alignment while the bone is secured with the plate, which is slipped under the groove in the upper blade without disturbing the position of the fragments. The operation thus becomes much easier and shorter and no assistance is required, except to help in bringing the fragments into apposition.



The forceps was made for me by J. H. Montague, 69, New Bond-street, W. 1.

K. F. D. Waters, M.B., B.Ch. Oxf.

St. Stephen's Hospital, Fulham-road, S.W.

Ladies' Medical Golfing Society. — Prizewinners for 1925 of the Open Bogey Competition in aid of the Royal Medical Benevolent Fund Guild are as follows: Best aggregate of five cards: (scratch), Miss I. Doxford, 16 down; (handicap), Class 1, Mrs. Atkins, 5 down; Class 2, Miss Magee, all square. Best single card: Class 1, Mrs. Hopkins, 6 up; Class 2, Mrs. Perry, 7 up. Best aggregate of two cards: (England) Miss E. Steel, 12 up; (Scotland) Mrs. Ritchie, 2 up. This competition was started in 1923 with the object of endowing a scholarship for the Royal Medical Benevolent Fund Guild. As this object has now been attained, the competition will be discontinued. The thanks of the committee are offered to all those players who have contributed to this successful conclusion.

THE LANCET.

LONDON: SATURDAY, DECEMBER 5, 1925.

MEDICINE AND MONOPOLY.

Sir **Donald MacAlister**'s presidential address to the General Medical Council[1] usefully re-published one elementary fact with which the medical profession is more familiar than is the lay public. Whatever else it may be, the medical profession is not a rigidly protected trade-union. There is a register of medical practitioners who, after certain years of prescribed training, have passed certain examinations and who may be said to have pledged themselves to maintain certain standards. In 1858, when the various branches of the profession were united under one governing body, Parliament created this system of registration because it was "expedient that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners." But, with the two exceptions of dentistry and midwifery, which Sir **Donald MacAlister** mentioned, there is no monopoly of practice in any of the healing services. We make no apology for elaborating this simple statement of the legal position. No woman may, habitually and for gain, attend women in childbirth (except, of course, under the direction of a qualified medical practitioner or in emergency) unless certified and enrolled under the Midwives Act; the prohibition is backed by a fine of £10. No person (save for certain obviously necessary exceptions) may practise dentistry, unless registered under the Dentists Act; the prohibition is backed by a fine of £100. But in creating the machinery of registration for medical practitioners Parliament has never said that no one is to give medical or surgical treatment unless his name is on the Register maintained by the General Medical Council. The registered medical practitioner has no more monopoly than the registered veterinary surgeon. Exclusion from the Medical Register is not exclusion from practice.

Hence in the present state of the law, as Sir **Donald MacAlister** reminded us, the man whose name is taken off the Register is as free to practise as if he had not been registered and the public is as free to employ him if they think fit. He escapes the jurisdiction of the Council and, if he has previously found difficulty in balancing himself upon the border-line of the recognised professional standards which the Council exists to maintain, he is happier if that feat is no longer required of him. There are, it is true, certain limited privileges which the unregistered practitioner does not enjoy. He cannot hold a medical appointment in the Army or Navy or in public institutions. He cannot give a medical certificate of illness, injury, or death; and he cannot prescribe a dangerous drug. If our countrymen think these restrictions are unfair to the unregistered, Parliament can abolish them. Meanwhile we can only repeat that, though a penalty awaits any unauthorised person who extracts a tooth or attends a woman in childbirth, nevertheless, in all other fields of medicine or surgery any person, whether registered or not, may perform any sort of operation upon the human body without liability, provided that his ministrations do not result in such untoward consequences as to give rise to a charge of culpable negligence. Even at this point, in the domain of civil and criminal liability for negligence, the law makes no difference whatever between the registered and the unregistered practitioner, the qualified and the unqualified. Probably judge and jury are more likely to find that treatment has been unskilful if administered by an unqualified person; to that extent a plaintiff brings his action against an unqualified person with better prospect of success than against qualified doctors and surgeons; but this bias, for what it is worth, arises from an inference of fact and not from a principle of law.

Let it not be said, then, that the medical profession is a jealously preserved trade-union. Do other professions have to tolerate like liberty of competition from unregistered practitioners? What opportunities of practice has the solicitor whose name is removed from the rolls of the Law Society? What right of audience has the barrister who is disbarred by the Inn which called him? There must be many members of the public who realise that more and not less protection is needed in the sphere of medicine and surgery. There must be many medical practitioners who, when they see their practice invaded by the unqualified, marvel more at the impotence of the General Medical Council than at the occasional exercise of its power of removal from the Register.

◆

THE MUSCULAR DYSTROPHIES.

The neurologist, perhaps more than any other specialist in the profession, is often called on to deal with diseased conditions not attributable to extrinsic morbid action but to intrinsic, possibly congenital, defect. Among the groups with which he is concerned none is at once more simple of recognition and more difficult of treatment than that of the muscular dystrophies. Clinical classification and description are doubtless essential as a step towards the problem of ætiology and of treatment, but in respect of this particular class of case they have not taken us very far. The essential clinical features of the majority of the dystrophies have been familiar for half a century, and although difference of opinion still exists as regards their interrelation we are not likely to reach any rational conception for treatment from clinical considerations alone. Nor, regrettably, can we rely with confidence solely on the observations of the histo-pathologist, for he handles dead material, muscular cicatrices from investigation of which it is well-nigh hopeless to expect the deduction of any data concerning incipient morbid action. The end-results of the myopathies and of the myelopathies, as far as the histological picture of the muscle substance is concerned, are for practical purposes not to be distinguished. Even when recourse is made to biopsy, microscopical examination reveals a pathological state but not a morbid process, while the interpretation of the actual tissue findings is not a little difficult.

It is not to be wondered at, therefore, that dissatisfaction with mere clinical description and with the limitations of morbid anatomy should lead the neurologist who has imaginative curiosity to tackle the problem of the muscular dystrophies from other viewpoints. Prof. **Edwin Bramwell**, whose Bradshaw lecture on this subject appeared in our columns last week, is to be congratulated on breaking away from neurological commonplaces and on his ingenious and suggestive endeavour to find an ætiological basis for these myopathic degenerations in disorder of the sympathetic and perhaps the neuroglandular systems. In brief outline of Prof. Bramwell's position, we may say that he is impressed by the idea that the muscles likely to be affected in the muscular dystrophies are those especially associated with the function of fixation, and he also supposes, relying on the observations of Babinski and Onanoff, that such muscles as develop early in the fœtus are especially predisposed to suffer myopathically; he takes the further view that those muscles which can be shown to have acquired their functions late or to have taken on new functions are likely to prove more resistant. Applying, in the next place, the dual innervation theory as elaborated in recent years by not a few workers, among whom the late Dr. Irvine Hunter holds a prominent position, the lecturer admits as an attractive speculation the possibility of muscular weakness and wasting being due to implication of the sympathetically innervated elements in muscle structure, and submits clinical instances which may be taken to indicate that, in some cases at least, disorders of the endocrine system coexist with muscular dystrophy, though he is inclined to attribute both of these to an (unknown) common cause, rather than to pronounce the latter secondary to the former.

---

[1] The Lancet, Nov. 28th p. 1133.

Undoubtedly the clinical data calculated to prove of most suggestiveness in this difficult problem are those which can fairly be taken to indicate, if not to demonstrate, that other systems than the muscular are involved. For example, the vasomotor mottling of the limbs often seen in pseudohypertrophic muscular paralysis, the somatic infantilism of not a few cases of the same clinical variety, and, indeed, their occasional trait of relative mental infantilism, the frequent smallness of the bones, and other points to which allusion might be made, all serve justifiably to make the clinician think of the interjection of a neural or neuroglandular factor in the dystrophic conditions usually held in these days to be intrinsically muscular in origin. An explanation of such phenomena must be sought. Insufficient attention has hitherto been directed by the neuropathologist investigating the morbid anatomy of the dystrophies to the state of the cells of the intermediolateral tract in the spinal cord, the central connexion of the sympathetic system, and when a cord is reported to be normal in a dystrophic case we may legitimately ask whether that tract has been specially studied. Even so, however, we do not feel that Prof. Bramwell is on firm ground when he leaves the non-muscular clinical symptoms above alluded to, to apply a questionable hypothesis to a somewhat doubtful clinical distinction. Is it, as a fact, the case that the muscles prone to degeneration are those especially connected with the function of fixation? What is fixation? Sherrington has shown us that the distinction between reflexes of posture and reflexes of movement is not clear-cut; we know that posture is often maintained voluntarily, and that movement is in reality a series of changes of posture. At one time a muscle may be employed kinetically and at another posturally. Prof. Bard, of Geneva, has in recent communications strongly urged the prima facie improbability of two separate mechanisms for fixation and for movement respectively; both on clinical and on physiological grounds the separation is more than a little doubtful. We wish Prof. Bramwell had referred to the implication of the facial musculature in myopathy; the remarkable selectivity, in the Landouzy-Dejerine type, of the circumoral and circumocular groups does not suggest any incidence on "fixation muscles." The specific difference, further, between the "myopathic smile" and the "myasthenic smile," scarcely supports a neuroglandular origin for the former disease if we accept it for the latter; or, alternatively, if it has its place in both conditions it will not by itself explain the clinical differences. The conclusion also drawn by the lecturer, that muscles with new or more recently acquired functions are relatively resistant, seems to run contrary to the general rule of involution as applicable to many other neural diseases with which the physician is familiar.

But the valuable service rendered by Prof. Bramwell in his Bradshaw lecture consists less in the sketching of hypotheses which are open to some criticism and for which a speculative rather than a definitely established basis is offered, since he himself admits with candour that speculation has its limitations; it resides rather in the courageous step he has taken of crystallising dissatisfaction with current views that describe but do not explain, and of applying to a large group of more or less intractable cases an analytical study on fresh lines which is bound to result in advance. His references to biochemical studies of the muscular dystrophies are comparatively few, although he has clearly envisaged the possibilities of progress in that direction; the now rather older work of Dr. E. I. Spriggs has been to some extent lost sight of, but the field is largely uncultivated and will repay any labour that is spent on it.

◆

RESEARCH IN SCHOOL MEDICINE.

We have already dealt[1] with the general features of Sir George Newman's recent report on the work of the school medical service during 1924. This report, like its predecessor, is no mere compilation of statistical facts and figures. Its pages present us with a living picture of the various branches of that work, its objects, its methods, its obstacles, its achievements, and even its deficiencies, and the whole is infused with a true spirit of idealism, modified only by such economical considerations in administration and organisation as the times make necessary. Throughout, the great aims of the service—prevention of disease, prevention of effects in adult life of disease in childhood, and the promotion of positive health—are kept steadily in view, and, as we read the report, we realise that its success in achieving these objects depends not only upon medical measures, but is intimately bound up with the solution of many social and educational problems. In some degree it is true to say that the school doctor discovers conditions whose causation it is beyond his powers to remove or to alleviate. Disease is found in the school-child which began in pre-school days, or if it only appears at the school age, owes its origin to hereditary causes and environmental conditions that have existed since infancy. Poverty, low wages, large families, bad housing, unsuitable and improperly cooked food, all play their part before the child enters school, and continue to do so during school life, and the persistence of these causes accounts for Sir George Newman's statement that "the number of sick children at the commencement of school life is as large as ever." In matters of dietary, insanitary school accommodation, and hygienic living conditions generally the school doctor can be active as an educationist, instructing either personally or through qualified teachers, the child, the teacher, the parent, and the education committees to whom he is responsible. It is a melancholy fact that too many of our elementary schools are still models of what a school ought not to be, and that the hygiene teacher may have to give his lessons in buildings which violate in almost every possible way the principle he is trying to inculcate. To some extent the same is true of school meals. There is great scope for educative work here, and the report shows that it is not being neglected.

---

[1] The Lancet, Nov. 21st, p. 1077.

One of the most interesting sections of the report is that dealing with research work. Ever since the inauguration of the school medical service, individual officers have in such time as they could spare from routine work carried out investigations on special lines, and this report describes some of the more important of these in 1924. The subjects discussed include Rheumatic Infection in Childhood, Goitre, Prevention of Defective Vision Resulting from Squint, Epidemic Encephalitis, Methods of Measuring Fitness, Effects of Infantile Ailments upon Teeth. Obviously, the efficiency and accuracy of result of such work is limited by the fact that the medical officer is only dealing with conditions in his own area, and would be greatly increased if the research was extended to include many areas with differing types of school population. The Board has now instituted a scheme for coördinated research to make this possible, and already four extensive investigations are definitely in being on Enlarged Tonsils and Adenoids, Causes of Defective Vision, Determination of Anthropometric Norms, and Mental Deficiency. For each subject a committee has been formed, consisting of medical officers of the Board, school medical officers, and other experts on the subject, and this committee draws up a schedule of investigation for the use of the medical officers who are asked to take part in it. The methods as described are very comprehensive and include the study of "control" cases. It is proposed, for example, in studying tonsils and adenoids, to inquire minutely into their origin and their earliest symptoms and signs, and also to carry out a following-up investigation over a period of years of cases detected, whether treated or untreated.

It is to be hoped that local authorities will pay heed to Sir GEORGE NEWMAN'S remarks on the importance of research work. As he remarks, "Every year to examine the bodies of a million children without thinking, without building new knowledge, would be a species of mechanical labour, the essential value of which would be lost." The school medical service has an unrivalled amount of material to its hand for purposes of research, and while the routine duties of inspection and treatment of the individual child must not be neglected, local authorities will do well to cultivate the larger vision, and give opportunity to their staffs to partake in such work as is likely to be of benefit to the child of the future.

ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.—The forty-sixth meeting of the Commission was held at the Home Office, Whitehall, on Nov. 26th, Sir Arthur Worley, and later Lord Lawrence of Kingsgate, in the chair. Evidence was heard from the National Confederation of Employers' Organisations (represented by Mr. J. B. Forbes Watson and Mr. John A Gregorson) on the financial aspects of the health insurance scheme. The Confederation submitted that the present need for relief to industry so as to stimulate employment was so urgent as to warrant a reduction in the weekly contributions of the employers and workers; that the present scheme is over-financed; and that the progressive expenditure on additional benefits is more than this country can afford and more than can be justified on any international comparison. Thereafter, the Commission sat in private to continue their review of the evidence which has been received since they began their work and to consider the questions arising therefrom. Proof copies of the oral evidence and the relative statements submitted at the meetings of Oct. 22nd, 23rd, and 29th, and Nov. 5th (the forty-first, forty-second, forty-third, and forty-fourth days) are now on sale at H.M. Stationery Office, price respectively 1*s.* 6*d.*, 2*s.* 3*d.*, 2*s.* 3*d.*, and 1*s.* 6*d.*

Annotations.

"Ne quid nimis."

VITAL STATISTICS FOR 1924.

THE first part of the Registrar-General's Statistical Review,[1] which has just been issued, contains tabular matter only, the explanatory medico-statistical comments being reserved for future publication. Certain items of medical interest may, however, be culled by those trained in the use of figures. The decline in the rate of infant mortality during the present century remains the outstanding feature of our vital statistics; a reduction from 139 deaths of infants per 1000 deaths in the lowest quinquennial record of last century to 90 in 1916–20 and to 75 in 1924 meaning an improvement phenomenal in extent. It is customary to regard the improvement in infant mortality as limited almost exclusively to the last nine months of infancy, and as being unshared by infant life in the first month after birth. This point cannot be checked historically from the tables in this report, which deals almost solely with the year 1924; but it can be tested geographically from the summarised tables as are given on p. 48. Thus in the aggregate experience of all county boroughs infant mortality at ages under 4 weeks was 31 per cent. higher than it was in the metropolis, and in the aggregate experience of all rural districts was 19 per cent. higher than it was in London. These are average results; and the experience of individual districts in and out of the metropolis separately stated on p. 59 shows much wider ranges of difference. Even the average figures, however, demonstrate how large a part of so-called neonatal mortality is preventable and is being prevented in some parts and not in other parts of the country. The statistics of maternal mortality from childbirth form a further subject of great medical interest. So far as the whole country is concerned, the only historical comparison year by year given in this review is based on the use of rates per million females living. Thus stated, the reduction of mortality from puerperal sepsis from 72 in 1914 to 50 in 1924 requires checking by rates based on the number of births in connexion with which the sepsis occurred. If any importance can be attached to notifications of puerperal fever, there has been no decline in this period. More utilisable evidence is derived from the comparison of total childbirth mortality and mortality from puerperal sepsis given in the review for 1923 and 1924, and correctly stated per 1000 births. The largest ranges of total puerperal mortality for 1924 are from 8·85 in the Isle of Wight, 5·12 in Merionethshire, and 5·01 in Montgomeryshire, to 1·43 in Kesteven and in Northamptonshire, 1·50 in Middlesex, and 1·84 in London. In county boroughs total puerperal mortality ranged from 0·97 in West Ham, 1·14 in Oxford, 1·23 in Huddersfield, 1·30 in Northampton, and 1·30 in Tynemouth, to 4·55 in Blackburn and 5·36 in Bolton. In some of these towns the rates are based on a relatively small experience; but even when this is remembered, there can be no reasonable doubt that the standard of medical and midwifery attendance on women in childbirth is lamentably lower in some areas than in others.

From the point of view of ready comparisons for long periods Table 6 on p. 35 is the most valuable. Typhoid and typhus fever have disappeared from this table, and their place has been taken by tuberculosis; the addition is more welcome than the omission. A second page of long-period comparisons for individual diseases would enhance the value of the review. Perhaps the most impressive items in the existing table are the decreasing toll of measles and whooping-cough on child life. It would certainly appear that these diseases, as causes of death, are being more nearly controlled than in the past; and this appears to be so, even when the possibility of disease cycles of varying virulence is kept in mind. Medical officers of health will regret the belated issue of the sickness notification statistics in this volume instead of in a separate volume, issued not later than April, as was formerly the case. The chief value of these sickness figures lies in the possibility of early comparison between different parts of the country, and the 11 months required to ensure accuracy and completeness in the death returns is a long time to wait.

SEX GLANDS AND ENDOCRINE FUNCTION.

SIX lectures given at the Serotherapeutic Institute of Milan have just been reprinted in book form.[1] The course was designed to elucidate the following problems: Whether there is in the sexual glands an endocrine as well as a generative function; whether it is possible, by transplanting the glands, to utilise their hormones; and whether it is possible to isolate from these glands an active substance like adrenalin or insulin. The subject-matter of these lectures may be briefly set out thus:—

1. *The Sexual Characters, their Cause and Biology.*—Prof. C. Champy, of the Faculty of Medicine of Paris, describes his experiments on salamanders (*Triton alpestris*), in which by starvation (alimentary castration) a sexual inversion is produced. In birds, if a functioning left ovary is excised, the right gland becomes transformed into a testicle and secondary male characteristics appear. He further shows that, while the testicle secretes an exciting hormone which influences the development of the comb in the cock, the horns in the ram, the beard in man, and the thumb gland in the frog, there is also an inhibitory substance in the ovary, a "kalone," which prevents the growth of a comb in the hen. He emphasises the law of "all or nothing." Partial castration shows that there is no direct proportion between the mass of the genital gland and the action of the hormone. This law, as also the existence of an ovarian kalone, shows the necessity of reserve in interpreting the negative experiments of castration in invertebrates in which it can never be certain that some small residuum of the genital gland is left. Hence the hormone acts as a catalyser, the kalone as an inhibitor.

2. *The Laws of Action of Internal Secretions.*—Prof. E. Gley, of the College of France, also describes experiments on cocks to ascertain the relation between the volume of the testicle and length of the comb. He found that the animal with large testicles had a no more perfect comb than one in which a mere nodule remained. He consequently disbelieves in hypo- or hyper-function of the endocrine glands. A given secretion, however, may really be a complex of various products. The substance which determines sexual characters may not be the same as that which presides over the development of the cock's comb, and the thyroid substance which acts on the psyche, may not be identical with the substance which regulates the skeleton. If a given internal secretion is composed not of a single but of several products, and if one of these should be wanting either temporarily or permanently, a dissociation of morphological and functional phenomena would ensue. Cases of partial myxœdema are satisfactorily explained on this hypothesis. Another law of great physiological interest is that of "functional constancy," as shown in the retrogression of sexual characteristics in castrated cocks, characters which can be preserved by the injection of testicular extract at regular intervals.

3. *The Anatomical Basis of Ovarian Correlations.*—Prof. A. C. Bruni, of the Veterinary Institute at Milan, works out the thesis that the production of a morphogenetic hormone capable of stimulating the development of certain characteristics and preventing that of others cannot be ascribed to one part of the ovary rather than to another, but to the whole organ. The thecal and interstitial cells, besides being deposits of nutrient material, are an intermediary between the germinal elements and the somatic. The ovary on this hypothesis would act like other endocrine organs pouring into the blood useful products and abstracting harmful ones.

4. *Correlation between the Psychic System and the Sexual Glands.*—Prof. E. Lugaro, of the University of Turin, gives an interesting summary of the psycho-sexual development of the child, calling attention to pre-puberty misogyny which, in his opinion, is not a "repression" but a temporary redundance of sensuality through virile psychic tendencies. The effect of early castration is a certain degree of infantilism, but no deviation towards femininity. Genius is not a pure sexual characteristic. Discussing dementia præcox, Prof. Lugaro thinks that Mott's researches point to a phase of exhaustion of glandular activity that happens in these patients when, after a period of extraordinary exaltation, the sexual function ceases for ever, nor does he agree with Freud that the delirium, hallucinations, and sexual images are due to a psychogenic mechanism. He attributes mental disturbances at the menopause to thyroid and not ovarian influences, and hyperæsthesia sexualis to other causes than the sexual glands. As to sexual perversion, he thinks the sexual glands only play a part through the generic factor of precocious and exaggerated erotism.

5. *Old Age, and Rejuvenation by Grafting.*—S. Voronoff, of the Laboratory of Experimental Surgery in the College of France, discusses the cause of old age. Unicellular animals reproduce by fission, old age and death do not occur. Higher up in the scale the somatic cells have definitely lost the aptitude of reproducing the complete organism, but can only reproduce parts as in hydra and lumbricus. In the vertebrates even the power of reproducing parts is lost and it remains for the sexual cells to reproduce the species. Old age is due to hardening of the tissues and organs by fibrous material by which the quantity of functioning cells is diminished. The endocrine glands through their hormones act on the nutritive metabolism, on the evolution of the cells, and on their morphology—if they cease to function life becomes impossible. Observations on castrated animals show that testicular hormone directly influences morphological change in all parts of the body, as much of the brain cells as of the epidermis, bones, and other tissues. Such animals when not slaughtered do not live as long as others. Eunuchs become old at 60 and do not live long. Opotherapy only offers a slight palliative to insufficiency or suppression of endocrine glands. Hence the importance of grafting. Prof. Voronoff describes his experiments with grafting testicles on old rams and bulls which recovered not only sexual power, but all the other qualities of young animals. He shows photographic representations of several men, bulls, and rams before and after testicle grafting, claiming that the internal secretion of a young testicle in an old organism activates the multiplication of cells and their metabolism from which results a true rejuvenescence of the body. He claims that the beneficial results of these graftings both in animals and men lasted several years. The photographs are without doubt very striking.

6. *Reactivation of Physical and Mental Force.*—Max Thorek, chief surgeon at the American Hospital in Chicago, deduces from his experiments that the seminiferous and Sertoli cells play no part in the production of libido, sexual power, or sexual characters in the male, but that only the interstitial cells of Leydig have this power. He arrives at this conclusion from the grafting of testicles previously "interstitialised" by X rays. He describes his technique, the peculiarity of which consists in "fenestrating" the tunica albuginea with the actual cautery. He gives a table of the results of 143 cases—in 63 per cent. there was return to a normal condition, while 22 per cent. were unsuccessful. The cases included senility, dementia præcox, neurasthenia, and hypogenitalism. He protests against the prominence given to restoration of sexual function; what is aimed at is the general reactivation of physical and mental force.

These six lectures, written by men who may be considered masters in their special subject, are worthy of careful study. It is to be regretted that they have not as yet been translated into English so as to increase the number of their readers.

BACTERIAL CONTENT OF FÆCES.

IT has long been recognised that living streptococci are practically always present in the fæces of healthy persons. Considerable doubt, however, exists as to the importance that should be attached to variations in the number of colonies of these organisms obtained on plate culture. There are those to whom their occurrence in numbers even remotely approaching those of the coliforms justifies the attribution of pathological activity and the exhibition of a vaccine. Variations in the bacillary forms occurring in the fæces have come in for a good deal of investigation, particularly in America. The influence of diet in this respect is now well recognised, the standard example being the passage from the infantile to the adult type of flora consequent upon the passage from a milk to a mixed diet. That the reverse change from a mixed to a milk diet may in the adult bring about a return to the infantile type of flora has not been so widely recognised, and instances are not wanting in which organisms appearing in the fæces as a result of the ingestion of a diet adopted for the treatment of a disease have been accredited with the causation of the condition. Even more slowly has knowledge accumulated as to the factors governing the streptococcal population of the fæces. This question has lately been investigated by Dr. A. P. Garrod [1] at St. Bartholomew's Hospital with interesting results. Dr. Garrod has been able to demonstrate quite clearly the importance of at least two factors determining the length of survival of streptococci in the fæces. One of these is diet. On a diet rich in carbohydrate streptococci appear in far greater numbers in the fæces than they do on one consisting mostly of proteins. This was well shown by the investigation of the fæces of patients on a modified Allen diet, who showed only 3·3 per cent. of streptococcal colonies on culture as compared with 40 per cent. in individuals on an ordinary diet. In this connexion Dr. Garrod found that whereas streptococci preponderated in the fæces of the horse they were almost absent from those of the lion. A factor even more potent in modifying the number of living streptococci in the fæces is the rate of passage of the intestinal contents through the gut. The more rapid the passage towards the rectum the greater the number of living streptococci appearing in the fæces. This point is illustrated in the accompanying graphs showing the effects respectively of a course of aperients and a course of morphia upon the streptococcal population of the fæces.

DOSAGE IN ULTRA-VIOLET THERAPY.

THERE is no less need for a practical method of measuring the doses of radiation used in ultra-violet therapy than in X ray or radium therapy. While nothing is easier than to specify theoretical units, so dear to the heart of the physicist, it is quite another thing with practical units. An illustration of this is the fact that if international agreement on the question of practical X ray units for medical purposes is reached next year, as it probably will be, it is only after 25 years of use of X rays in treatment. In the early days of light therapy, when Finsen was establishing its utility, quantitative methods, apart from the specification of the power consumed by the lamps, were not usual. At present there is a widespread use of open arcs with carbon or tungsten electrodes and of enclosed arcs of which only the mercury vapour type has any considerable vogue. With an open arc of a given type carrying a certain current at a given voltage there may not be much room for big variations in output of radiation during the running of a lamp, but with the mercury-vapour lamp there are two phenomena which preclude a uniformity of output. It has been shown by B. D. Watters that very soon after a mercury-vapour lamp is started the output of radiation diminishes and then increases to a steady level. The degree to which this happens depends on the power applied to the lamp, and the time taken to reach a steady condition may be as long as 15 minutes. The second phenomenon is the increasing opacity of the quartz container in the course of time. If, then, for no other reasons, it will be seen that, in order to know anything definite about the output of radiation from the mercury-vapour lamps, we must measure the radiation emitted by it and not only the power supplied to it.

But the need for some practical method of measurement for both open and closed arcs comes still closer home to clinical investigators who wish to compare their results with those of others in a strictly quantitative way. For practical purposes the method of measuring dosage should be rigid and yet easily practised, while the instrument itself should be portable, robust, and not too costly. The instrument described on p. 1205 by Mr. H. D. Griffith and Dr. J. S. Taylor consists of a cadmium photo-electric cell coupled up with a direct reading electroscope. When the rays from either of the sources mentioned fall upon the cadmium surface, electrons are liberated from the cadmium in quantity proportional to the intensity of the incident rays, and the emission of these electrons is indicated by a movement of the gold leaf of the electroscope. It appears from the description that the instrument fulfils a number of the requirements just mentioned, and it will be interesting to have the experiences of others when the instrument is in general use. The authors, wisely we think, refrain from claiming that the instrument is especially sensitive to that part of the radiation of greatest therapeutic efficiency. As a matter of fact, such terms require much qualifying before they can be scientifically used. Luminous and ultra-violet rays are now used for a very large variety of diseases, and whereas one complaint may benefit from radiation selected from one part of the spectrum, another may be more effectively treated by a different selection. It is not yet certain whether it is beneficial to apply heat radiation simultaneously with rays of low heat equivalent or whether the claim for the antagonistic action of different wave-lengths is substantiated in full. There is room for much investigation in this most promising field of radiotherapy, and it will be helped by methods which are, at any rate, quantitative in aim.

THE DIAGNOSIS OF DYSENTERY THROUGH THE MICROSCOPE.

A CONCISE, informative, and well-illustrated article of some 37 pages, recently published,[1] sets forth the pathology, gross and minute, of bacillary and protozoal dysentery. The method of cytodiagnosis, originally described by Willmore and Shearman,[2] forms the basis of the paper and has been elaborated so as to enable a rapid diagnosis of bacillary dysentery to be made from a microscopical examination of the discharges from the bowel. Should cultural methods of isolating the dysentery bacillus be solely relied upon, in a very high proportion of cases the information will be misleading. In presenting the subject in a manner which can be understood and practised by physicians and laboratory workers in countries where the two main forms of dysentery are rife, this paper has great practical value. The object throughout the paper is to correlate the pathological changes in the bowel wall with the nature and appearance of the cells which appear in the fæcal exudate. Many of the cells, notably the macrophages or clasmatocytes, seen in the fæces of bacillary dysentery closely resemble, to the uninitiated, stages in the life-cycle of *Entamœba histolytica*, and it naturally follows that a great deal of unnecessary confusion has risen with regard to the differential diagnosis, so important from the point of view of treatment, between these two conditions. A close study of the points of differentiation in the cell picture, as set forth in this paper, should dispel any doubts forthwith. A clear account of this subject was badly needed. The microphotographs of the cells which illustrate this article are striking and convincing. The section on treatment, which runs on familiar lines, is admirably handled.

RESPIRATION IN ANÆSTHESIA.

THE Dental Board are conferring a benefit by their series of post-graduate lectures on General Anæsthesia, and the benefit will be a great one if the other lectures maintain the standard set up by Prof. Yandell Henderson, who started the series in London, Manchester, and Edinburgh. His subject was control of respiration in anæsthesia by inhalation of CO_2. The lecturer showed how by scientific employment of carbon dioxide as a respiratory stimulant safe and rapid induction of anæsthesia can be assured, and also rapid elimination of the anæsthetic drug with consequent diminution of after-effects, particularly those attributable to so-called acidosis. The practical anæsthetist will naturally not see eye to eye with all the statements of one whose observations are mainly conducted in the laboratory, and the general picture of an open administration drawn by Prof. Henderson is fortunately a caricature of the usual clinical induction. Nevertheless, the lecturer's deductions from his laboratory work and from the phenomena which are sometimes witnessed in the anæsthetising room are sound, and the lines which he lays down for conduct are of value and full of suggestion for the practising anæsthetist. Naturally the latter will have to adapt his doctrine to the circumstances of reality. For example, the principles advocated and demonstrated by Prof. Henderson can only be carried out with apparatus which involves the use of a closely applied face-piece. In practice there are many individuals for whom the one horror of anæsthesia is any device of this sort. These people are not merely fussy or neurotic. Either retching or an intolerable sense of suffocation attacks them when a face-piece is closely applied, and their peculiar disability has to be met of course by some gradual form of administration. These people are not amenable to the lecturer's first rule of good anæsthesia, which is, he states, rapid induction. The second is uniform concentration of vapour, and the third rapid termination. The most important lesson which he enforced, and with which every anæsthetist will agree, is that control of the breathing is the most essential of all factors in securing successful anæsthesia. Respiration, moreover, it was pointed out, should not be regarded merely in terms of rate of breathing. Pulmonary ventilation is what really matters, and the depth of the breathing is therefore as vital as the rate. It is the volume of air breathed per minute that is the important quantity. In this connexion Prof. Henderson dwelt on the great work done by Prof. J. S. Haldane, who has explained the significance and relations of the volume of air breathed. Carbon dioxide, he showed, is the normal stimulant and regulator of breathing. The supply of oxygen has relatively little influence on respiration, and the administration of this gas alone never acts as a respiratory stimulant. This stimulating effect of carbon dioxide on the respiratory centre is put to practical use in the methods recommended by Prof. Henderson for securing rapid induction of anæsthesia. Another factor of the method is that the ether used is fully vaporised before it is administered. Rebreathing is employed because more uniform concentration of the vapour can be thus attained than in any other way. The condition of surgical anæsthesia depends on nothing else but the concentration of the anæsthetic in the central nervous system. The degree of saturation of the rest of the body has no direct influence on anæsthesia. The concentration of ether in the brain is immediately determined by that in the lungs and in the blood. The anæsthetic tension of ether in the blood is 3·7 to 4 per cent. of an atmosphere, which comes to about 1·2 g. of ether per litre of blood. The anæsthetic concentration is probably the same for everyone, even the most alcoholic. The reactions prior to anæsthesia are the real variables as between different patients, not the concentration at the point of full anæsthesia. The practical problem, then, is how ether can be volatilised and the vapour passed into the lungs rapidly enough to raise the concentration in the arterial blood immediately to the full anæsthetic amount. This could only be achieved with normal breathing if the concentration of the ether vapour inhaled were extremely high. This method has indeed been employed, but is undesirable for one reason, because of the irritating effect on the lungs of these highly concentrated vapours. The problem resolves itself into this: how can 6 or 8 g. a minute of ether be introduced into the pulmonary blood, or how can 9 or 12 g. of ether per minute be introduced as vapour into the inspired air without increasing the concentration of ether in this air to more than about 5 or 6 per cent. ? Obviously to introduce a large amount at a low concentration only one way is possible—by a large volume of breathing. This is achieved by stimulating respiration, by means of carbon dioxide, up to several times the ordinary resting volume, and then running in a sufficient concentration of fully vaporised ether to produce the concentration of ether in the blood necessary for full anæsthesia. Prof. Henderson pointed out also the value of carbon dioxide administration in cases of alcoholic poisoning, of drowning, and during the recovery period of anæsthesia. He claims it for an absolutely demonstrated fact that inhalation of air or oxygen to which a considerable percentage of carbon dioxide has been added is of very great benefit alike after a prolonged anæsthesia and after asphyxiation.

THE HOSPITAL SAVING ASSOCIATION.

IT cannot often have happened that any novel organisation, whatever its purpose, has progressed with the rapidity of the Hospital Saving Association which held its third annual meeting last week. The figures of its growth are, indeed, remarkable. In July, 1923, it had 15,000 members; by January, 1924, the numbers had grown to 25,000; by January of the present year they had swollen to 101,000; July saw 160,000, and there are now more than 200,000. A year ago the income of the Association was under £40,000; it is now £120,000. These figures go far to justify Lord Hambleden's forecast at last week's meeting that the membership will in time reach a million. The material for expansion is almost unlimited. Persons whose incomes are within "hospital limits" increase yearly in number, and there are, no doubt, still eligible many who have not yet joined the Association. For 3*d.* a week, some portion of which is often paid by the employer—the London Midland and Scottish Railway Company, for instance, contribute one-third—a man may ensure hospital treatment for himself and his family without loss of self-respect and with complete freedom from almoner's inquiries into means. Where so much can be obtained for so little it is not surprising that the movement should have achieved such rapid and substantial success. Nor are the benefits one-sided. Like the quality of mercy, these small payments are twice blessed, for if they give a remarkably cheap insurance on the one hand, on the other they provide the hospitals with large sums which they would otherwise almost entirely lack. During the past year the hospitals have received £65,000 from these weekly pence, a substantial proportion of which has been paid for extra benefits. Thus, while the contributor learns a little lesson in thrift he is rewarded with the best and fullest treatment that the modern hospital can provide. The fear that these easy terms would attract to the hospitals, to the detriment of the general practitioner, cases which would otherwise not have been treated there has been falsified, and may apparently now be dismissed. Mr. E. W. Morris's optimistic statement that the Association has "saved the hospitals" is, perhaps, a trifle premature, but it is well on its way to the achievement of the object for which it was created. This and other forms of contributory schemes are not only placing hospitals generally on a sound financial basis, helping to make possible the inevitable and costly developments of the near future, and giving the quietus to hasty talk about State interference, but inculcating valuable lessons of thrift, self-help, and independence among the mass of the people.

THE COLLEGE OF SURGEONS AND ITS MEMBERS.

The Council of the Royal College of Surgeons of England is again considering the claim of Members of the College to representation on its Council. A few days ago the Council received a small delegation introduced by Dr. Redmond Roche, President of the Society of Members, who set out the story of the long unrequited desire of the Members to have a share in the government of a corporation in which they were numerically so preponderant. Ever since the charter of 1843 which instituted "a new class of Members who were to be called Fellows," on whom devolved the government of the College, there has been almost continuous protest by the remainder against this exclusion. In 1887 the Association of Members presented to the Privy Council a petition signed by 4660 Members, believed to be half the number which could then be reached by post, and in 1896 a half-yearly meeting of Fellows of the College passed a resolution admitting the desirability of giving Members direct representation on the Council. At every annual meeting for the last 31 years the Society of Members has urged this concession upon the President, and at the recent meeting, which we briefly reported, a motion to that effect was moved by Dr. L. Haden Guest, M.P., and seconded by Mr. F. Lawson Dodd, L.D.S., both Members of the College, in speeches which dealt with broad principles of democratic government. Dr. Guest spoke of the vast new store of knowledge and capacity available to the College which might be opened up by linking the general body of Members with the work of the institution, and Mr. Dodd spoke of the greater authority, the wider sanction, and the greater influence in the eyes of the public which the College would gain thereby. It was, he thought, refreshing in these days to have children coming forward and wanting closer union with their parents. No criticism was made by the Members' representatives of the conduct of the Council as at present elected and administered by Fellows of the College, for the charter of 1843, which excluded a large class from governing, removed the existing abuses of government. The number of the Council was then increased to 24, of whom three should retire annually, the choice of examiners was no longer restricted to councillors themselves, and any councillor became eligible for presidency or vice-presidency. The Council of the College as so constituted now carries out a triple function of developing the Hunterian Museum, of maintaining a valuable library, and of examining candidates in surgery. Other functions are less well defined. Section XV. of the College by-laws states that the Council will at all times protect and defend its Fellows and Members who may be disturbed in the exercise and enjoyment of their rights; and Section XIV., relating to the admission of Members, includes a declaration by them to obey every lawful summons issued by the Council and to maintain the dignity and welfare of the College. It may be that with the growth of wider professional associations and the institution of a disciplinary medical council the medico-political work of the College of Surgeons was likely to be dropped. In any case, since the conjoint method of examination was initiated in 1875, any political action might have to be taken with the coöperation of the sister College. It may also be contended that the term "Member" does not now entail more or other obligations than that of "Licentiate" of other medical corporations. But there is no reason to doubt that a body of Members is desirous of taking part in the corporate life of the College, and that this desire is to be considered on its merits by the Council. There may be other and larger issues than those which have appeared in the fitful light of controversy.

CENTENARY OF BIRMINGHAM MEDICAL SCHOOL.

The centenary of the Medical School of Birmingham University will be celebrated on Dec. 8th, when it is proposed to confer honorary degrees on Mr. Neville Chamberlain, Minister of Health; Sir Donald MacAlister; Sir Humphry Rolleston; and on Mr. Priestley Smith, the doyen of the medical profession in Birmingham. The first records of any teaching in medicine in Birmingham go back to 1768, when Mr. John Tomlinson, surgeon to the Town Infirmary, held a course of anatomical lectures during the winter season for the medical students apprenticed to medical practitioners in the town. Tomlinson was the first provincial surgeon to give regular anatomical lectures, and his name should be handed down to posterity on that account. The General Hospital was founded in 1779 by Dr. John Ash, who became one of its first four physicians, the other three being Dr. Smith, Dr. Withering, the introducer of digitalis into practical medicine, and Dr. Edward Johnstone, who died in 1851 at the age of 94. The seed of the modern flourishing and important school was planted on Dec. 1st, 1825, when William Sands Cox, then 24 years of age, delivered the first of a series of anatomical lectures. Clinical lectures had been delivered long before this in Birmingham, but Cox introduced the systematic instruction of medical students at No. 24, Temple-row. Cox had studied himself at the General Hospital, and after being articled to his father had continued his studies in London at Guy's and St. Thomas's Hospitals, obtaining the M.R.C.S. in 1824. He then went to France, where he studied under Laënnec, Lisfranc, and Cuvier, and where he met Quain, the anatomist. On his return to Birmingham Cox urged the formation there of a school of medicine, and in 1828 the senior members of the local medical profession decided to follow the lead given by Manchester and Leeds. In spite of much opposition the school was fairly started by 1834, when 90 students were enrolled. Two years later King William IV. accepted the position of patron and conferred upon the school the title of the Birmingham Royal School of Medicine and Surgery. In 1843 a charter granted by Queen Victoria resulted in the renaming of the school as Queen's College. When Cox retired in 1865 the College was still heavily in debt and its future uncertain, but three years later it joined forces with the Sydenham College connected with the General Hospital. Later, after the foundation of Mason Science College, some of the preliminary medical training was transferred there, and in 1892 the medical faculty of Queen's College became the Queen's Faculty of Medicine to Mason College. The final step was the incorporation in 1897 of Mason College as a University College, the charter conferring University status being granted three years later. During the present century the growth of the medical faculty has continued unchecked, a flourishing dental school has arisen, and the outstanding event has been the opening of the new buildings at Edgbaston by

King Edward VII. in 1909. A short history of the School, compiled by the medical faculty and the Birmingham Medical Institute will be published [1] on the day of celebration.

THE PSYCHO-PHYSICAL BORDERLAND.

NOT so long ago there was a curious borderland between psychology and physiology which was apt to be the despair of the psychologist and the derision of the physiologist. The convinced experimentalist looked rather askance at inquiries which on the one hand were hardly objective and on the other seemed little different from his own field in the brain and special senses. But, as Sir Charles Sherrington pointed out in his anniversary address to the Royal Society on Nov. 30th, there has lately been a divergence and separation of interests and methods which is likely to make for progress on both sides. Psychology is more sure that it is really possible to investigate fruitfully the workings of the mind by means of the mind, and is more content to leave the synonymy of brain and mind for the time being in the air. Physiologists at the same time have been pursuing the analysis of the behaviour of the higher animals in terms of physiology and without any reference to the psychical factors which are involved, and they have made much progress in interpreting behaviour in terms of the principles of reflex action. Pre-eminent in this advance in natural knowledge are Pavlov and Magnus. Prof. Magnus, Croonian lecturer to the Royal Society this year, shows, for example, that a cat without cerebral hemispheres will respond to the stimulus of seeing a mouse by putting itself in the completely appropriate posture to leap in the right direction on to the mouse. The reaction is a complicated postural reflex similar in precise purposiveness to that by which a cat achieves "rightside-upness" when it is thrown out of the window. It brings the animal up to the point where it has to decide whether it will jump at the mouse or not; this it cannot do without more brain than it has. Prof. Pavlov and his pupils have taken up the problem at this stage as an act of behaviour, and in their study of conditioned reflexes have shown that the final outcome is the sum of impelling and restraining impulses which are determined partly by the circumstances of the moment—and especially by their time relations—and partly by the circumstances under which the act has been elicited in the past. This line of inquiry comes very near psychology, but it is pursued with a strict avoidance of all reference to psychical reactions. Indeed, it leads to a group of facts which is obviously common ground to psychologists and physiologists, and that they now approach this meeting point each from their own side and each with their own axioms and fundamentals is plainly a gain from which much may be hoped for. Both parties can now look on the insoluble riddle of the relation of brain and mind as their possible goal rather than as the point from which each must start out; to look for what you cannot see is more hopeful than to start from an unknown place.

WE regret to announce that Sir John MacAlister, for 38 years secretary of the Royal Society of Medicine, died at his home in London on Dec. 1st. A memorial service will be held at St. Peter's Church, Henrietta-street, Cavendish-square, on Saturday, Dec. 5th, at 1 P.M., to be followed by a private cremation at Golders Green. The House of the Royal Society of Medicine will be closed on that day from 12.30 to 2.30 P.M.

---

[1] Birmingham: Cornish Brothers. 2*s*. 6*d*.

A KINDLY THANK-OFFERING.—The patients, friends and neighbours of the late Dr. W. R. Kirkness, of Pembury, Tunbridge Wells, who died on Sept. 19th, have subscribed the sum of £330 as a very small appreciation during the past six years, and in memory of his self-sacrificing devotion to duty.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CL.

THE TREATMENT OF RUPTURED MUSCLES AND TENDONS.

A MUSCLE or its tendon may become lacerated either subcutaneously or as part of an open wound. The following remarks are confined to subcutaneous rupture.

A muscle is usually torn as the result of a sudden and almost involuntary contraction, and the tearing may be partial or complete. The most common site is the junction of the tendon with the fleshy fibres, but the tendon itself may snap or be separated from its attachment, sometimes carrying with it a fragment of bone. A common symptom is sudden pain as though the limb were struck with a cane; the snapping of the tendon may be heard at the same time. But frequently the only symptom noticed is the weakness of the limb. The muscles or tendons most often ruptured are the tendo Achillis, ligamentum patellæ, quadriceps extensor, plantaris, adductor longus, biceps cubiti, and extensor tendons of fingers. These, too, are the muscles most frequently involved in the injuries of athletes.

Rupture of the Tendo Achillis.

The heel tendon is the most frequent to rupture. The injury occurs when the tendon is subjected to any sudden or forcible strain, of which dancing is a traditional example. A gap can be felt between the divided ends, but by bringing the foot into the attitude of equinus the interval is lessened and good union always takes place under proper treatment. I know of no instance during the last 12 years at the Royal National Orthopædic Hospital, where tenotomies are very frequently performed, where union failed after tenotomy of the tendo Achillis for congenital talipes—and this in spite of the fact that the tendency is deliberately to increase rather than diminish the gap after section. In treating this condition there is no need to make the patient lie up. All that is necessary is to raise the heel of the boot by adding half an inch of leather and to prevent movement at the ankle. This is accomplished by attaching a rigid metal rod to the heel of the boot and running it up behind the leg to terminate in a padded leather calf band which buckles to encircle the limb just below the knee. The patient will quickly accommodate himself to this appliance and walk with the limb rotated outwards. To keep the ankle quiet in bed at night a splint should be worn with foot and calf pieces so arranged as to keep the foot in slight equinus. Daily massage of the calf muscles with the foot grasped and held in the equinus attitude will help recovery and maintain muscle tone.

Another simple and efficient method is that devised by Lynn-Thomas through personal experience of the injury. A flattened strip of aluminium is moulded to the dorsum of the foot and front of the ankle and leg. It is then encased in a thick indiarubber tube and is worn between the tongue of the boot and the lacing, the lower strands of the boot-lace being made to encircle the splint to avoid undue pressure. The metal and rubber do not extend upwards much beyond the boot. The appliance may be discarded at the end of six weeks; by then the ends of the tendon will be united by strong white fibrous tissue.

If the tendon has parted from its insertion and taken with it a fragment of bone it is best to cut down and explore, and replace the fragment either by bone-pegging or suturing with kangaroo tendon. The appliance described above should be worn after about 14 days until bony union is established.

Ligamentum Patellæ.

This tendon is usually torn in a strong effort to avoid falling backwards. It may break in the middle or at either end, in which case it is not uncommon for a piece of bone to be detached at the same time. The rupture is more often complete and the patella is retracted well upwards. In partial rupture the patient should be kept off his feet for a fortnight or longer, according to the severity of the injury, with the knee extended on a splint. A pad should be applied above the knee and bandaged so as to keep the patella pushed downwards. The extensor cruris group of muscles should be massaged daily, for they incline to waste rapidly in any serious injury about the knee-joint. In complete rupture the best treatment is to operate. The same precautions are necessary as when the knee-joint is explored. The joint capsule will be found torn and will require suturing. The tendon should be repaired with strong catgut. If a tibial or patellar fragment has been avulsed it should be reattached by wire or kangaroo tendon. For three weeks after the operation the limb is kept on a bed calliper with a knee-cap and a pad to keep the patella pushed downwards. When the patient is about to get up it is a wise precaution to have his bed calliper converted into a walking calliper, which he should wear for another fortnight or so. Daily massage should be given during the whole time, and when he begins to get up—i.e., three weeks after the operation—active and passive movements of the knee are commenced.

Quadriceps Extensor Tendon.

This muscle is torn in much the same way as the patellar ligament. Owing to the attachments of the expansions of the vasti to the patella and tibia, it is unusual to find a wide separation of the ends. The treatment is the same as for the patellar ligament —i.e., explore and suture the divided ends after removing blood from the joint and closing the capsule. The after-treatment is also the same. In the elderly, or where for some reason the operation is ill-advised, a good result may still be obtained by wearing the bed calliper with knee-cap and pad for six weeks or so, and then, when up and about, a walking calliper for a further period of six to eight weeks.

Plantaris (" *Lawn-tennis Leg* ").

What is commonly called " lawn-tennis leg " has been variously attributed to laceration of one or more of the following structures: the plantaris, soleus, inner head of gastrocnemius, aponeurosis, and deep plexus of veins. Therefore at best the diagnosis is speculative. The most typical symptom is a sensation of being struck by a stone on the calf, followed by weakness of the leg. The limb swells, and sooner or later there is a patch of discoloration due to extravasation of blood. On palpation a gap may be felt in the aponeurosis of the leg with distinct local tenderness. The limb should be treated by raising it for a few minutes to allow the veins to empty as much as possible. Brown holland strapping is then applied in overlapping strips of about an inch and a half wide, extending from just above the ankle to the upper part of the calf. The plaster bands should not encircle the limb completely; there should be an inch gap in front. The patient should then be told to walk freely. He may hesitate in bringing his heels down, but he should be encouraged to do this and to walk with a full step. The strapping will be loose in three or four days and should be then reapplied. The plaster is renewed at intervals up to a fortnight or longer until the patient has recovered sufficient confidence to dispense with it.

The essential points in the treatment are the splinting of the lacerated tissue by the plaster and the patient's own active movements. Massage is unnecessary.

Adductor Longus (" *Rider's Strain* ").

Rupture of the adductor muscles of the thigh is an injury to which hunting men are liable. It is produced by the sudden grip of the saddle when taking a fence or in controlling a restive animal. A hæmatoma of varying size develops and underneath a gap can be felt in the muscle; there is frequently pain and discomfort which may extend to the perineum, and in a day or two there is considerable discoloration. The treatment should first be directed towards dispersing the swelling and relieving the pain. This is best done by gently massaging the area from below upwards. A pad of wool is then placed over the seat of the injury and pressure maintained by a bandage applied in spica fashion. The massage is kept up for three or four days, and then the limb is strapped and the patient encouraged to move about.

The rest of the treatment resembles that of " lawn-tennis leg." Quiet riding may be resumed in a fortnight.

Biceps Cubiti.

The biceps is torn more frequently than any other muscle in the upper limb. The rupture occurs during violent contraction in either the short or the long head or in the belly. Of three cases in my experience, one occurred whilst coal-mining, another during a climb in the Alps, and the third when carrying a load. This last case was characteristic. Two soldiers were carrying a plank when one of them accidentally dropped his end, and the other, suddenly lurching forward, felt something give way in the arm. All three patients complained of weakness in flexing the forearm. There is no difficulty about the diagnosis; on contracting the arm a prominent lump forms in front in striking contrast to the other limb; where only one head is torn this is retracted, leaving a groove where the tendon sheath only may be palpated, with the undamaged head running alongside.

Owing to the great tendency to retraction, massage is of little avail; the only satisfactory treatment is to operate and suture the torn muscle. Of the three cases cited two refused operation and no improvement resulted. The third had the muscle exposed and the inner head was found ruptured with the lower end coiled up. The sheath was intact for its greater part. The upper end of the tendon was pulled down inside its sheath and the two ends united by catgut. The arm was nursed in the flexed position on a splint for ten days, when massage and passive movement were commenced and the splint retained for another ten days. After that the patient was allowed gradually to use the arm and recovered completely.

Extensor Tendons of Fingers (" *Mallet Finger* ").

The finger extensor tendon is frequently torn by a blow on the end of the digit. This occurs in the cricket field and amongst housewives when making up beds. The terminal phalanx drops with inability to extend it. The tendon is often only partially torn or the fibrils frayed. The best treatment is to splint the finger for three or four weeks according to the severity of the injury. A duralumin splint half an inch wide and extending from the finger-tip to the head of the metacarpal is applied with strapping and padded with wool. An extra small pad of wool is applied between the splint and the tip of the finger to promote slight hyperextension of the terminal phalanx. This splint is worn for ten days and then a shorter splint reaching to the web of the fingers is applied. When the splint is left off the finger is massaged and active movements commenced gradually and increased until full voluntary extension is possible.

GENERAL MEDICAL COUNCIL.

Dental Examinations.

At the session of the General Medical Council held last May it was decided that certain resolutions of the council on dental examinations should be forwarded to the various licensing bodies, who should be asked to comment upon them. On Nov. 24th the Dental Education and Examination Committee of the Council presented its observations on the replies received. One of the recommendations of the Council was "that, where possible, candidates should be tested in the mode of administration of general anæsthetics in common use in dental practice and should be required to perform extractions." It was reported that in the final examination the University of Birmingham has no practical tests in the administration of anæsthetics and that the Universities of Liverpool and Manchester do not require candidates to perform extractions. At the Royal College of Surgeons of England a certain number of candidates is always called upon to extract teeth under anæsthetics in the final examination, but this test is only applied to a small proportion of the whole number examined. The Council of the Royal College of Surgeons of England strongly disapproves of candidates under examination being called upon to administer anæsthetics to patients. Having considered the answers received the Dental Education and Examination Committee recorded its opinion that—

> The test of performing extractions in the final examination for a dental qualification is as important as the other practical tests required by all the licensing bodies; and that, when circumstances permit, it would greatly add to the efficiency of the examination if candidates were tested in the administration of anæsthetics in common use in dental practice, carried out under the personal supervision of the examiners. If the anæsthetics be administered by a skilled anæsthetist the candidate should be questioned on the mode of administration, and the possible dangers which may arise therefrom.

A regulation making it obligatory to pass all the dental subjects of the final examination at one time is apparently enforced by all the licensing bodies except Manchester University; whilst the recommendation that candidates remitted in any subject of a professional examination should, before being readmitted to examination therein, produce evidence of further study in this subject, is not carried into effect at Queen's University, Belfast. The Royal Faculty of Glasgow suggests that this further course of study should be asked only of those who obtain less than 40 per cent. of the available marks. The Council decided that the application of the regulation should not entail a period of remission of more than six months, and directed that the attention of licensing bodies should again be drawn to its resolutions and to the observations on them contained in the Dental Education and Examination Committee's report.

The Dentists Register.

A communication was read stating that the Dental Board had considered the case of John Begg, which had been referred back by the Council for further inquiry, and had not found that his name ought to be erased from the Register. A report was also received from the Board concerning Thomas McGowan, registered as of 26, Whalley New-road, Blackburn, who was convicted of a felony at the Liverpool Assizes on Oct. 30th, 1925, and sentenced to 12 months' imprisonment. The solicitor to the Board presented the facts to the Council, which deliberated in camera and directed that Mr. McGowan's name should be removed from the Register.

The President then announced that the Registrar to the Dental Board had been directed to restore to the Register the names of Stuart Christopher Nicol and James Edward Smyth.

The Medical Register.

The Case of Alexander Dawson Reid.—This case was adjourned from Nov. 27th, 1924, when Mr. A. D. Reid, registered as c/o R. Crosbie, Barclays Bank, High-street South, London, E. 6, appeared before the Council on account of convictions for drunkenness. The charges against him were then proved to the satisfaction of the Council, but in consideration of evidence that he was suffering under physical disabilities and of an assurance from Mr. Reid that he would henceforward refrain from alcohol, the Council postponed its decision for 12 months. Testimonials as to sobriety during this period were received, and Mr. Hempson, solicitor, who appeared on behalf of the Medical Defence Union, stated that Mr. Reid had kept his promise to abstain from drink. After deliberation in camera, the President announced that the Council had not seen fit to direct that Mr. Reid's name should be erased from the Register.

The Case of John Evans.—On Nov. 26th, 1924, Mr. Evans, registered as of 6, High-street, Yiewsley, Middlesex, appeared before the Council on a charge of having issued 79 medical certificates required for National Health Insurance purposes during the period Sept. 5th, 1922, to March 11th, 1924, without having seen the insured person to whom they referred at any time between these dates. The Council at that time postponed judgment for 12 months. Letters from practitioners testifying to the good conduct of Mr. Evans during the interval having been produced, the Council considered the case in camera and the President announced its decision as follows—

> "Mr. Evans: As I warned you a year ago, the Council takes a very grave view of any laxity on the part of a registered medical practitioner in giving Certificates, a privilege which is entrusted to him by the State in the belief that he will exercise it honourably; but, having had good reports of your conduct since November last, the Council are now satisfied that you will be more careful in the future and do not see fit to direct the Registrar to erase your name from the Medical Register."

The Case of Alexander Duguid.—The Council then considered the case of A. Duguid, registered as of 20, Meadow-road, Leeds, M.B., Ch.B. Aberd., who appeared on the following charge:—

> "That, being a registered medical practitioner and a lieutenant in the Royal Army Medical Corps, you were tried by a Field General Court Martial, held overseas on July 14th, 1917, on the following charge, viz.: when on active service drunkenness, in that you, at Mikesse on June 30th, 1917, having been warned for the duty of accompanying patients to Morogoro, were drunk, of which charge you were found guilty, and sentenced to be dismissed from His Majesty's Service; and that in relation thereto you have been guilty of infamous conduct in a professional respect; and that you were at the Leeds City Police Court convicted of the following misdemeanours viz.: On May 2nd, 1922, of disorderly behaviour while drunk, for which you were fined 10*s*. or seven days' imprisonment; on April 24th, 1925, of being found drunk and incapable, for which you were fined 10*s*. or seven days' imprisonment."

Mr. Duguid was accompanied by Mr. O. Hempson, solicitor, who was instructed by the Medical Defence Union. Mr. Hempson objected to the two offences of which his client had been convicted at the Leeds City police court, being classed as misdemeanours under Section 29 of the Medical Act, 1858. A misdemeanour, he argued, is an offence, less than a felony, which is the subject of indictment. The offences in question had been the subject of summary jurisdiction, and therefore should not be regarded as misdemeanours. The Council could only deal with them, he considered, under the heading of "infamous conduct" and not under that of "convictions." The Council's solicitor quoted authority to the effect that any crime less than a felony is a misdemeanour, whether indictable or not, and the President, on the advice of the Council's legal assessor, overruled Mr. Hempson's objection.

In the course of examination Mr. Duguid stated that on June 30th, 1917, he was off duty; he had transferred the care of his patients to a relieving officer and he had not been warned for duty as alleged. On May 2nd, 1922, he was one of a wedding party at a railway station, and although he had "had a drink" he was by no means drunk. He was taken to the police station and pleaded guilty to the charge in order that the incident might be closed as soon as possible; but he had resolved to abjure alcohol and had been a total abstainer ever since. The conviction on April 24th, 1925, was, he stated, the result of an error. On the previous night he had taken large doses of dial—8 or 10 tablets—for insomnia, and this had made him unwell. In the morning he called in a fellow practitioner, who advised him to stay indoors for 48 hours; but this advice he disregarded. He went out, was overtaken by faintness, entered a cab, and was driven to the police station. Neither on this nor on the previous occasion was he examined by a police doctor. Mr. Hempson produced letters of testimonials to Mr. Duguid's character, and the Council deliberated in camera. The President then announced that the charge and convictions had been proved to the Council's satisfaction; nevertheless, in view of the evidence submitted, the Council had not seen fit to direct that Mr. Duguid's name should be erased from the Register.

The Case of Charles Bertrand Wagstaff.—Mr. C. B. Wagstaff, registered as c/o National Provincial Bank, 50, Cornhill, London, E.C. 3, M.R.C.S. Eng., L.R.C.P. Lond., was charged with having abused his position as a medical practitioner by committing adultery with a married woman, with whom and whose family he stood in professional relationship, of which adultery he was found guilty by a decree of the High Court of Justice, dated June 11th, 1925. Mr. Wagstaff did not appear in answer to his notice, but wrote saying that he denied that adultery took place, but realised that it would be impossible to prove the contrary to the Council. Evidence of Mr. Wagstaff's attendance in a professional capacity on the persons concerned having been put forward, the Council considered the case in camera and the President announced that the Registrar had been directed to remove his name from the Register.

The Case of George Joseph Mary Fraser.—Mr. Fraser, registered as of 36, Blenheim-crescent, London, W. 11, and having the Irish Conjoint qualification, appeared to answer the charge that he had been convicted on Oct. 21st, 1924, of failing to notify a case of tuberculosis and the birth of a child, and—

> "That, being a registered medical practitioner you, by your presence, countenance, advice, assistance, or coöperation, knowingly enabled an unqualified and unregistered person, viz., one Ulric Knyvett Hoff: (1) To attend, treat, or perform operations upon patients in respect of matters requiring professional discretion or skill, or otherwise to engage in professional practice as if the said person were duly qualified and registered; (2) to issue certificates, notifications, reports, or other documents of a kindred character in your name or on your behalf. That being a registered medical practitioner: (1) You signed a certificate of death on April 3rd, 1924, of one Mrs. Sarah Jenner, certifying that you attended her during her last illness, and that you last saw her alive on March 30th, 1924, whereas you had not attended or seen the said Sarah Jenner during her last illness at all; (2) you signed a certificate of death on Feb. 8th, 1925, of one Mrs. Amelia Wimmer Lembo, certifying that you had attended her during her last illness, and that you last saw her alive on Feb. 8th, 1925, whereas you had not attended or seen the said Amelia Wimmer Lembo during her last illness at all; (3) you signed a certificate of death on Feb. 12th, 1925, of one Mrs. Elizabeth Whiting, certifying that you attended her during her last illness, and that you last saw her alive on Feb. 12th, 1925, whereas you had not attended or seen the said Elizabeth Whiting during her last illness at all, which certificates were untrue, misleading, and improper; and that in relation thereto, you have been guilty of infamous conduct in a professional respect."

Mr. Charles Davis, solicitor, of the firm of Bulcraig and Davis, conducted Mr. Fraser's defence, and the hearing, which began on Tuesday, did not end till Thursday, Nov. 26th. In brief, Mr. Fraser's answer to the charge was that he never had any reason to doubt that Hoff was a qualified and registered practitioner until Feb. 8th, 1925, when Hoff informed him that he was not on the Register. He denied that the certificate of the death of Mrs. Sarah Jenner given on April 3rd, 1924, was in any way inaccurate; but admitted that, under the stress of circumstances, he gave the two other death certificates without having attended the patients as stated. He did not know that Hoff was unqualified until March 31st, 1925, some time after they had parted company.

Mr. Fraser's statements were to the following effect. In 1911, about the time of his qualification in Dublin, he was introduced to Hoff by a member of the honorary staff of his hospital. Hoff stated that he had a medical degree of Calcutta University and invited Mr. Fraser to act as his assistant and locum tenens on a tea plantation in Bengal of which he was medical officer. Mr. Fraser served in India in this capacity for more than a year and then returned to start a practice in Mile End-road, London, which he later left to serve in the war. In 1918 he received a call from Hoff, who acted as his assistant for a time. In January, 1924, he bought a practice in Kensington and on meeting Hoff in Southampton-row in a destitute condition invited him to act as locum tenens. Mr. Fraser was at times crippled by sciatica and the arrangement seemed satisfactory. Hoff had been acting as house physician at Doncaster and Hartlepool Infirmaries and elsewhere, and produced brilliant testimonials from a large number of doctors all over the country to whom he had acted as locum tenens or assistant. It never occurred to Mr. Fraser to question his qualifications or registration, and he engaged him at eight guineas a week. Later the remuneration was reduced to four guineas without night work. Hoff proved thoroughly competent, and the word registration was never mentioned between them until Feb. 8th, 1925, when Hoff suddenly appeared and asked Mr. Fraser to come and see Mrs. Lembo, whom he was attending, and who was dying. Dr. J. S. Goodall had been called in as a consultant. Hoff now admitted that he was not, in fact, registered though he was qualified for registration. (It was later discovered that he had taken a part of his examination for the licence of the Apothecaries' Hall, Dublin, and that whilst employed during the war at the institutions mentioned he had been granted by the Registrar-General a temporary privilege of signing death certificates for patients dying in these places.) Mr. Fraser and Hoff hastened to Mrs. Lembo's house, only to find the patient dead. It seemed impossible to ask Dr. Goodall for a certificate in case his suspicions should be aroused. Mr. Fraser was ill at the time. He thought it best to sign the certificate himself, pending Hoff's registration, and, having done so, he returned to his nursing-home. Four days later Mrs. Whiting died whilst under Hoff's care. Mr. Fraser again thought that the only possible course was to give a certificate himself. These two certificates were, he stated, his only lapses. On Saturday, March 14th, 1925, Mr. James Fenton, M.B., medical officer of health for the Borough of Kensington, had reason to make inquiries about a case of alleged scarlet fever said to be under Mr. Fraser's care. He called at the house, but was told that Mr. Fraser was in a nursing-home and that Hoff was acting for him. Hoff was out, but it occurred to Mr. Fenton to look up his name in the Medical Directory. On finding that it did not appear he rang up Hoff and told him of the omission. Mr. Fraser said that on returning home that day (Saturday) he heard of the incident and insisted that Hoff should accompany him to see Mr. Fenton on the following Monday morning. Mr. Fenton was then told that Hoff was not on the Register (although entitled so to be) and from March 14th onwards, said Mr. Fraser, Hoff and he had nothing to do with one another except in connexion with debts and defalcations which Hoff had incurred in the practice.

In support of Mr. Fraser's case evidence was brought of the respect in which he and Hoff were held by their patients, and Mrs. Eileen Fraser testified to the circumstances under which her husband visited Mrs. Jenner on March 30th, 1924. In support of the charge the Council's solicitor called the daughter of the late Mrs. Jenner, who denied emphatically that it was possible for Mr. Fraser to have called on the deceased on March 30th, 1924, without her cognisance. Cross-examined, Mr. Fraser admitted that he had not examined the patient or recommended treatment and was uncertain as to who let him into the house. It was stated that no record of the visit had been made. The Council's solicitor then drew attention to an incompatibility in the statements of the defence. He quoted a declaration made by Mr. Fraser at Scotland Yard to the effect that when Hoff visited him in Mile End-road in 1918 he knew that Hoff was not registered, and also drew attention to a letter sent to the Council on Mr. Fraser's behalf by his solicitor in June last in which it was stated that Mr. Fraser was aware of this fact in 1922. In reply to cross-examination on these points Mr. Fraser said that both statements were incorrect. The first was made under the influence of nervousness, and the second was a result of confusion of dates.

At the conclusion of the hearing the Council deliberated on the case in camera, and the President announced that the charges had been proved to the Council's satisfaction and that the Registrar had been directed to erase Mr. Fraser's name from the Register.

The Case of Andrew George Tottenham Hanks.—Mr. Hanks, who is registered as of Edith-grove, Chelsea, London, S.W., and holding the Irish Conjoint qualification, appeared upon a charge of having been convicted of drunkenness on several occasions. He was not charged with infamous conduct in a professional respect. Mr. Hempson, instructed by the Medical Defence Union, appeared on Mr. Hanks's behalf and formally objected, as on a previous occasion, to the charges being brought under the part of the Medical Act, 1858, which relates to convictions for misdemeanours. His objection was overrruled. It was stated that at the age of 51 Mr. Hanks had served in France as a Territorial and had been invalided home, since when he had been in poor health. In January, 1922, he had fallen from his horse and injured his head, and the illness and accident had made him very susceptible to alcohol. Since July last, however, he had been a total abstainer. Letters were read from doctors and others stating that before his health was damaged Mr. Hanks was an abstemious man, and testifying to his high character, and after the Council had considered the case in camera the President announced that judgment would be postponed until May next in order that evidence might be produced of satisfactory conduct in the intervening period.

The Case of Algernon Randolph Upton.—Mr. Upton, registered as of Medina Villas, Hove, M.R.C.S. Eng., L.R.C.P. Lond., appeared before the Council on the charge—

> "That, being a registered medical practitioner and whilst acting as locum tenens for Theodore Charles Pocock, a registered medical practitioner, and subsequently thereto, you sought to attract to yourself patients and to promote your own professional advantage: (1) By inviting panel patients of the said Theodore Charles Pocock to become panel patients of yours; (2) by filling in your name on the medical cards of panel patients of the said Theodore Charles Pocock, without being authorised so to do, in order to have them transferred to your panel; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

Mr. F. W. Gentle appeared as counsel for Mr. Upton, instructed by Mr. F. W. A. Cushman, solicitor, whilst the complainant, Mr. T. C. Pocock, M.B., was represented by Mr. Ray Neve, his counsel, instructed by Messrs. Dell and Loader, his solicitors.

In the spring of 1924 Mr. Pocock was compelled to enter a sanatorium, and it was suggested to him that he should retain Mr. Upton, the son of a neighbouring practitioner, as his locum tenens. Without making any special inquiries he fell in with the suggestion; there was no agreement that Mr. Upton should not later enter practice in the neighbourhood if he wished. At this time Mr. Upton was not on the panel, and in order to regularise the position an arrangement was made in October, 1924, that his name should appear as that of Mr. Pocock's deputy. The engagement ended on April 29th, 1925, when Mr. Pocock came back to his practice and the two parted on good terms. Later, however, Mr. Pocock received a list of the names of 73 patients who had removed their names from his panel and on making inquiries discovered—so he alleged to the Council—that Mr. Upton had been asking some of his patients whether they would like their names transferred to his panel, and that the doctor's name on the patient's card had in two cases at least been changed without the patient's consent. In support of these charges a number of witnesses was called. Several members of a family named Boone stated that Mr. Upton had been called in to see a child at their house and had told them, without being questioned, that he was going to start practice in the town and "that he already had a good few patients of Dr. Pocock's and would be glad to have the Boones on his list if they felt like making a change." One member of the family present at the time was unable to confirm the details of this conversation and said that she could not be certain whether she had heard this remark. Other witnesses stated that they had been invited to change to Mr. Upton's panel, and evidence was also tendered by a man who said that he had left his card at the surgery and had received in its stead a new card bearing Mr. Upton's name, although he had never authorised any such change. In the course of cross-examination Mr. Pocock said that he had been a candidate for municipal election, and whilst admitting that he might have offered the literature of his party to patients who came to see him, denied emphatically that he had ever allowed bottles of medicine to go out from his dispensary with the words "Vote for Pocock" written on them, and disagreed with the suggestion that a considerable number of patients had been alienated by his canvassing for his party. He was quite unaware, he said, that Mr. Upton had been in practice in Hove before acting as his substitute. Mr. Upton said that he had been a surgeon-lieutenant in the Navy and had served in the Indian Medical Service. After leaving India he had returned home and for two years had conducted a small private practice in Hove from his father's house. He denied absolutely the charges that had been made against him. He had never invited any patient of Mr. Pocock's to transfer to his panel, and the statements of the witnesses who asserted the contrary were not expressions of the truth, but of personal bias in favour of Mr. Pocock and against himself. The fact that cards had had the name of the doctor altered to his own was immaterial. Whether they were actually in the name of Pocock or of Upton, they were credited to Mr. Pocock, just the same, according to the arrangement by which he served as deputy on the panel for Mr. Pocock. He had started practice on May 1st, 1925, with only one panel patient of his own, who had transferred himself previously without any suggestion that he should do so.

At the close of the hearing on the following day, another witness tendered evidence on Mr. Upton's behalf and the Council considered the case in camera. The President then announced that the facts alleged against Mr. Upton had not been proved to the satisfaction of the Council.

The Case of Edward William Dacre Hardy.—Mr. Hardy, registered as of Durley-road, Bournemouth, M.R.C.S. Eng., L.R.C.P. Lond., appeared to answer a charge of having, between June 30th, 1924, and April 16th, 1925, sent 31 prescriptions for morphia tablets (to be supplied on three occasions) and morphia suppositories to a woman who had been his patient during May and June, but whom he never saw after June 24th, 1924; the giving of these prescriptions being an abuse of the privileges conferred on medical practitioners by the Dangerous Drugs Act.

Sir Travers Humphreys conducted the case on behalf of the Director of Public Prosecutions. He said that although the Home Office had no feeling against Mr. Hardy, whose record of practice was very creditable, it disapproved of his attitude towards what he had done. Mr. Hardy stated that the patient, Mrs. Coke, came under his care at Bournemouth in May, 1924. For the previous 16 years or so she had been suffering from cystitis and rectal pain and had become addicted to morphia, but under the care of a doctor the daily dose had been reduced to 2 gr. Mr. Hardy attempted to reduce the dose further, but this proved impossible, and when in June the patient said that she was going to London for about six weeks and was most anxious not to be transferred to another doctor, he agreed to send her prescriptions for this minimal quantity of the drug, thinking that the arrangement would prevent the patient taking her own measures to satisfy the craving. For the same reason he continued to send prescriptions, and as he often heard from Mrs. Coke did not realise that so long a time had passed since he had seen her. In February, 1925, she went to see Mr. G. E. Cope, to whom she gave Mr. Hardy's name as that of her medical attendant, and correspondence was exchanged. Mrs. Coke died on April 23rd, and at the inquest death was stated to be due to hydronephrosis and uræmic coma, accelerated by chronic morphia poisoning, together with local peritonitis and pneumonia. The coroner said that he hoped that Mr. Hardy was ashamed of himself, but Mr. Hardy replied: "No, Sir, I am not." He now realised, he said, that his action might have led to Mrs. Coke receiving the morphia ordered by him in addition to that prescribed by some other doctor, and that it was not a proper thing to have sent the prescriptions. Sir Travers Humphreys said that this was a very fair explanation. Dr. D. Hyla Greaves appeared as witness to Mr. Hardy's high character, and, amongst others, a testimonial was received from 35 members of the honorary staff of the Royal Victoria Hospital, Bournemouth, and another from the Bournemouth division of the British Medical Association, of which Mr. Hardy is chairman. After the case had been considered in camera the President said that the Council took a very grave view of any abuse of the privileges conferred upon medical practitioners under the Dangerous Drugs Acts, which involved a trust by the Government in the honour and good faith of the profession. The Council had already given notice that any contravention or any abuse of the privileges, whether it were criminal or not, constituted an offence of which the Council would take notice. The Council regarded the facts alleged against Mr. Hardy as proved, but, having regard to the warning he had received during the proceedings and to his assurance as to his conduct in such matters in the future, the Council trusted that his conduct in reference thereto would henceforth be beyond reproach. Accordingly it had not seen fit to direct the Registrar to remove Mr. Hardy's name from the Register.

The Case of William Lloyd.—On Saturday, Nov. 28th, the Council considered the case of Mr. Lloyd, registered as of Brook-street, London, W., L.S.A. Lond., L.R.C.P. and L.R.C.S. Edin., and L.F.P.S. Glasg., who appeared at the complaint of the British Medical Association on the following charge:—

> "That, being a registered medical practitioner, you sought to obtain patients and to promote your own professional advantage by means of an article published in the *Daily Mail* of June 5th, 1925, entitled 'Hay Fever—New Treatment—Specialist's Report—Patients Cured,' which was based upon materials supplied by you; and sought to obtain as patients certain persons who, after reading the article, had written to the *Daily Mail* for your name, and whose letters were forwarded to you by the *Daily Mail*, and to whom you wrote inviting appointments to be made for treatment, although they had not themselves communicated with you; and that in relation to the facts so alleged you have been guilty of infamous conduct in a professional respect."

Mr. W. E. Hempson appeared for the complainant and Mr. J. B. Melville was counsel for Mr. Lloyd, instructed by Messrs. Cooper, Bake and Co., solicitors. A number of members of the Council who are members of the British Medical Association took no part in the proceedings.

An article was read which appeared in the above-mentioned newspaper of June 5th, 1925, and purported to describe the remarkable results obtained by a London specialist in the treatment of hay fever. The article was written in a "popular" manner and contained derogatory references to common forms of treatment. These were given as coming from the specialist himself, as also were certain details of successful cases and of experiments proving that cured patients remained immune when exposed in hay-fields. Statutory declarations were made by three sufferers who had applied to the *Daily Mail* to know the name of the specialist. One of these said that in reply to his application he had received an undated typewritten letter from the news editor saying that he now had permission from the doctor referred to in the article to give his name to inquirers. Mr. Lloyd's name and address were appended. Later the witness had received a card, from Mr. Lloyd's address and signed by a secretary, stating that Mr. Lloyd would be pleased to see him by appointment and that his fees were four guineas and two guineas. A second witness had had an undated typewritten letter from the news editor saying that his letter of inquiry had been forwarded to the specialist mentioned in the article and had later also received an appointment card. One of the witnesses had communicated with the British Medical Association. On behalf of the Association Mr. Hempson said that in view of the large circulation enjoyed by the newspaper referred to it was hardly possible to imagine a more gigantic advertisement. The article read like the announcement of a quack. A letter from the manager of the legal department of the Associated Newspapers to the General Medical Council stated that Mr. Lloyd had made no objection to the article being written provided that his name was not mentioned and no indication of his identity divulged. The article had attracted considerable attention and a large correspondence, and many telephone calls had been received from readers. Unfortunately a subordinate member of the staff had communicated Mr. Lloyd's name to a limited number of inquirers and the writer of the article had asked Mr. Lloyd to see a few selected cases by appointment.

Mr. William Lloyd said that for some years he had been in consultant practice as a specialist in diseases of the throat, nose, and ear, and held various hospital appointments. He had a very large practice and enjoyed an income of many thousands a year. He had no possible motive for advertisement. On June 4th, 1925, he said, he had a visit from a journalist connected with the Associated Newspapers, who came as a sufferer from hay fever. During treatment he spoke of the work he was doing, and showed a book on hay fever which he had written some years ago and which had been withdrawn and was not now obtainable. The journalist took no notes, and was not given a copy of the book or any written information. When the treatment was over he said to Mr. Lloyd that he might write an article on it. Would there be any objection? Mr. Lloyd said that if an article was written, on no account must his name be mentioned owing to his enormous practice. The article appeared next day. Mr. Lloyd was so busy that he did not pay a great deal of attention to it; but he protested vigorously to the journalist on several occasions when he came for treatment, saying that to have published the article so quickly without letting him know was very unfair and had placed him in a very awkward position. Not a word in the article was his own, and though some of it was founded on his conversation during treatment, much of it bore no relation to anything he had said. In reply to the protests the journalist had smiled; eventually he had said he was sorry. Mr. Lloyd sent neither protest nor any other communication to the *Daily Mail*, but when the journalist asked him if he would care to see a few selected patients who had inquired about the treatment he replied that he would be willing to see anyone whom the journalist liked to recommend, and informed one of his two secretaries that appointments should be given to a few cases which the journalist might send. Mr. Lloyd himself was so busy that he dealt only with that section of his correspondence marked "Personal," and owing to a misunderstanding his secretary had given cards to all those persons whose names were sent from the newspaper's office. He was not in general in the habit of asking patients where they came from, and neither the journalist nor those whom he recommended enjoyed special terms. Mr. Lloyd denied absolutely that he sought advertisement or professional advantage from the publication of the article.

The Council deliberated in camera and the President announced that the facts alleged had been proved to the Council's satisfaction, and that Mr. Lloyd had been adjudged guilty of infamous conduct in a professional respect. The Registrar had been directed to remove his name from the Register.

The Case of Henry Thompson Keating.—Dr. Keating, registered as of the School of Hygiene, Mount Pleasant Avenue, Liverpool, M.D., C.M. McGill, appeared on Monday, Nov. 30th, on a charge of enabling an unqualified and unregistered person called Looker to treat a patient named Mrs. Hedges, or otherwise to engage in professional practice; and of having been associated for the purpose of obtaining patients with an unqualified or unregistered person who procures or sanctions the advertising or publication of notices directing attention to his professional skill. Mr. Le Brasseur appeared for Dr. Keating, and Mr. Hempson on behalf of the Medical Defence Union which was the complainant. Mr. Le Brasseur said that the proceedings were the result of an unfortunate coincidence. Dr. Keating served in a medical unit in New York in which Looker was a medical officer. He had never had reason to doubt his qualifications, either then or afterwards when Looker was engaged in medical practice in America. In August, 1925, he paid a social visit to Looker, who had come to London, and was asked to see Mrs. Hedges. He examined her and afterwards made arrangements for her to have an operation. On no other occasion was he connected with Looker's practice. Dr. Keating had not seen advertisements of the practice before he saw the case; he was unwilling to operate on Mrs. Hedges, and he had not the slightest intention of unprofessional conduct. Evidence was produced showing that Dr. Keating by illness had been prevented from ventilating his case in order to anticipate the charge being brought. After the Council had deliberated in camera the President announced that the charges alleged had not been proved to the satisfaction of the Council.

The Case of Joseph Stenson Hooker.—Dr. Hooker, who is registered as of 4, Spanish-place, London, W. 1, L.S.A. Lond., L.R.C.S. and L.R.C.P. Edin., M.D. Durh., appeared before the Council on the charge—

> That, being a registered medical practitioner, you have sought to attract to yourself patients and to promote your own professional advantage: (1) By associating yourself with the advertising and canvassing carried on through the medium of articles published in the issues of March 21st and 28th, April 4th and May 30th, 1925, of *John Bull*, relating to an alleged "consumption cure," known as the Newell treatment; (2) by sending circular letters regarding the "cure" to persons not under your charge, but whom you thereby hoped to secure as patients; (3) by endeavouring in your own advantage to induce registered medical practitioners to use in the treatment of their patients, and to make themselves responsible for a medicament of whose properties and action such practitioners were ignorant, while refusing to disclose to them the compositions or formula thereof. And that in relation to the facts so alleged, you have been guilty of infamous conduct in a professional respect.

Dr. Hooker was represented by Mr. Leon Freedman, his counsel, instructed by Messrs. Lattey and Hart, and the complainant was the Medical Defence Union, represented by Mr. O. Hempson, solicitor.

During March and April, 1925, a series of four articles appeared in *John Bull* dealing with the Newell Treatment for Tuberculosis. These articles stated that the inventor of the remedy had consulted a fully qualified West End specialist in tuberculosis (whose name could not be given owing to the rules of the General Medical Council), who had had a very high percentage of cures amongst his patients, and that a committee had been formed in London to investigate the new treatment. It was suggested in several of the articles that the negative attitude of officialdom and the conservative outlook of the General Medical Council and the Ministry of Health were responsible for holding up the distribution of the remedy to suffering humanity, and there were photographs in illustration of Sir Donald MacAlister, Mr. Neville Chamberlain, Sir George Newman, and others. Readers of the newspaper were encouraged to write to the editor, who would put them in touch with doctors who could give the treatment. Mr. Hempson produced evidence that a reader who had taken this advice received a letter to say that the inquiry had been passed on to the London doctors investigating the treatment and that he later had a typewritten communication, signed on behalf of Dr. Hooker, saying that if the inquirer's own doctor was unwilling to give the treatment it might be possible to direct him to a doctor in the district who could do so, or possibly it could be arranged that one of Dr. Hooker's own staff should give the treatment. A committee of duly qualified medical men was in constant attendance for such cases. Later the inquirer had a letter saying that on receipt of 2 guineas, a minimal sum arranged to cover overhead expenses and the high cost of the medicaments, Dr. Hooker would send to the patient's doctor enough of the remedy to last for a month. The treatment, it was stated, could only be given by duly qualified medical men. A manifesto to the medical profession was afterwards issued which stated that the remedy was not a secret remedy in the accepted sense since Dr. Hooker and other investigators were aware of its components. The promoters were getting on with the work of curing tuberculosis rather than facing carping critics. The remedy could be guaranteed as absolutely harmless. In a later letter Dr. Hooker said that there were now 600 medical practitioners using the treatment.

Dr. Hooker appeared before the Council in such poor health that he was unable to tender his defence in person and his counsel read a declaration on his behalf. He said that he had never sought to attract patients to himself by advertisement and that at his age such an intention would be unthinkable. He had received the formula of the remedy from the inventor in strict confidence, and though he had been very anxious to reveal its exact nature to the profession, he had not had the right to do so. He had formed the highest opinion of the value of the treatment and had been, and was, extremely anxious to place it in the hands of doctors who were attending sufferers from tuberculosis. The circular letter which had been quoted recommended inquirers to apply to their own doctors, and it was far from the intention of the committee to attract patients to themselves. The suggestion that patients might receive treatment from the committee was in the nature of a last resort, if it was quite impossible for them to receive it otherwise; but it had been pointed out to him that the letter might have a wrong interpretation put upon it, and he had instantly cancelled its circulation. Dr. Hooker then gave an account of negotiations with the General Medical Council and the Ministry of Health. The Council had refused to deal with the matter on the grounds that it was outside its statutory function. The Ministry had received the formula under the usual pledge of secrecy and had also had an account of cases which had been treated. Dr. Hooker was understood to say that negotiations with the Ministry were still in progress. The discoverer of the remedy had only consented that the formula should be disclosed to the Ministry on condition that this was done through the medium of *John Bull.* Dr. Hooker said that he had supplied materials for the articles only on the pledge that the name of no doctor concerned should appear. His whole object had been to get the medical profession, and the profession only, to try the valuable remedy.

Mr. Freedman said that his client had obviously been animated throughout by a great enthusiasm and by a belief that he could benefit humanity. Mr. Hempson said that the pledges under which the formula was revealed to the Ministry had made it impossible to broadcast the good news—if it were good news—about tuberculosis to the profession. He could not accept the suggestion that Dr. Hooker's conduct had been disinterested. The Council considered the case in camera and the President announced that the charges had been proved to its satisfaction and that the Registrar had been directed to remove Dr. Hooker's name from the Register.

The Case of Sesi Kapo.—The last case before the Council was that of Mr. Kapo, registered as of 49, Broad-street, Lagos, Nigeria, M.B., Ch.B. Edin., who appeared on the charge—

> That, being a registered medical practitioner, you conspired with one Albert Taiwo, by supplying to him a fictitious account of £25 for professional services alleged to have been rendered by you to the wife and child of the said Albert Taiwo, in order to enable the said Albert Taiwo to withdraw money from the Provident Fund of the Nigerian Railway, which he was not entitled to withdraw and could not withdraw without a detailed account signed by a medical practitioner. That in respect of such offence, you were tried with the said Albert Taiwo in the District Court of Lagos, and were on March 6th, 1925, convicted of conspiracy and of forging the said account, and were fined £50 or six months' imprisonment, which conviction was upheld on your appeal to the Supreme Court of Nigeria. That, by an Order made on June 15th, 1925, as the result of the said conviction, under Section 13 of the Medical Practitioners' and Dentists' Ordinance, Chap. 46, the Office Administering the Government in Council directed the Registrar of Medical Practitioners and Dentists to strike out your name from the Register. And that in relation thereto you have been guilty of infamous conduct in a professional respect.

The case was reported to the Council by the Colonial Office on information received from the officer administering the Government of Nigeria. Mr. Harper, solicitor to the Council, opened the case by quoting from the records of the trial held in Nigeria. Mr. A. Neilson, K.C., who appeared for Mr. Kapo, objected that it was impossible to bring as evidence an account of proceedings conducted elsewhere which were not in the knowledge of any member of the Council. Such an account was not evidence by itself unless witnesses were brought. It was unfair to read an account of a prosecution unless he, Mr. Neilson, had an opportunity to cross-examine the witnesses whose testimony had led to the conviction. The Council's solicitor replied that as the Council had no powers to summon witnesses or to swear them when they came, if the present objection were upheld it would be very difficult to try a case when the witnesses were outside the kingdom. Mr. Neilson said that the fact that the Council was a domestic forum, in which the Council was trying one of its professional brethren, did not make it permissible to try the case in a looser way than would be permitted in a court of law. The legal assessor to the Council said that it was proposed to prove that Mr. Kapo had been struck off the Nigerian Medical Register and convicted in Nigeria. On that evidence the Council would be entitled to strike the name off the Register, but an inquiry into the case was being made in order to discover whether there were extenuating circumstances. The fact that no witnesses appeared might affect the weight ot the information, but did not render it inadmissible. Evidence of court-martials held abroad was accepted. The fact of conviction was itself evidence which should be considered. Mr. Neilson asked to see the certificate of conviction, but this could not be produced. Mr. Neilson objected that production of the certificate was an essential preliminary to any proceedings. The President said that the Council was not treating the case as a conviction but on its merits.

The Council's solicitor then read part of the account of the proceedings held at Lagos which led to Mr. Kapo's conviction. The prosecution had suggested that Mr. Kapo's account for professional attendance was wholly fictitious and had emphasised the fact that a police search had failed to find any wife of Albert Taiwo whom Mr. Kapo had attended. Mr. Neilson examined Mr. Kapo in the witness-box. He gave particulars of his attendance on a woman said to be Albert Taiwo's wife and of the bill he wrote out for professional services after delivering her of a child. Mr. Neilson asked for the production of the bill, which was an important document at the Lagos trial. The Council's solicitor admitted that he could not produce it, which Mr. Neilson considered very unfortunate. Mr. Kapo denied that he had ever conspired with Taiwo or anyone else and that he ever had any reason to do so, and a testimonial to his character was read. In closing his client's case Mr. Neilson said that this was by the President's definition a new inquiry. Yet the prosecution had produced no one who could be cross-examined nor any of the relevant documents which were produced at the trial. The trial itself did not seem to have taken the clear course that trials take in England. No one had even suggested a motive for Mr. Kapo's single straying from the straight path. Why should a man imperil his professional career and an income of £500 or £600 for the sake of a share in £25 ? Why, for the matter of that, should Albert Taiwo have bothered to conspire to obtain £25 from the provident fund seeing that he would have to pay it back out of his wages ? As to the charge that the supposed wife of Taiwo was an imaginary person, the chief witness called by the prosecution—namely, Taiwo's " senior wife "—stated clearly that she had existed. The onus of proving the contrary—even if the prosecution had not accepted the evidence of its chief witness as it was bound to do—rested with the prosecution. The judge had admitted that it was just possible that Mr. Kapo had attended this woman, and if there was a doubt the accused should have had the benefit of it. The trial in Lagos, Mr. Neilson was sorry to say, appeared to have been hopelessly muddled. There were not materials before the Council to prove that Mr. Kapo had been properly convicted ; there had been many remarkable features about the proceedings, and no motive had been suggested.

After the Council's solicitor had replied the case was considered in camera, and the President announced that the facts alleged against Mr. Kapo in paragraph 1 of the charge had not been proved to the Council's satisfaction. (His name therefore remains on the Register.)

Restorations to Medical Register.

On Nov. 26th it was announced that the Registrar had been instructed to restore the names of Haydn Brown, Patrick Joseph Honan, Trevor Owen Williams, and William Mortimer Sheen to the Medical Register.

EXECUTIVE COMMITTEE.

The report of this Committee contains an account of the negotiations for the re-establishment of reciprocity with Italy referred to in the presidential address on Nov. 24th. Inquiry on the practice of medicine in this country by holders of foreign degrees elicited the information that reciprocity can only be established with a country in regard to which the King has by Order in Council declared that Part II.

of the Medical Act, 1886, shall apply. When reciprocal relations are established it becomes the duty of the General Medical Council to consider which medical diplomas granted in the said country shall qualify their holders for registration by the Council. At present the only foreign countries with which reciprocity exists are Italy and Japan. In view of the overcrowding of the medical profession in Austria it has been suggested that the emigration of Austrian doctors to foreign countries is desirable. It is understood, however, that no foreigner can practise medicine in Austria unless he becomes an Austrian citizen, and this condition, of course, precludes reciprocity. In reply to inquiry the Council stated that the number of British registrations "during this year and for the past two years has been considerably greater than usual, and some time will probably be required before the practitioners newly qualified in this country are absorbed into private practice and vacancies in the public services. It is therefore probable that foreign doctors would have some difficulty in establishing themselves satisfactorily in this country."

Public Health Committee.

The report of this committee deals chiefly with the new regulations for the Diploma of Public Health, which require that candidates shall receive instruction over a period of not less than 12 months subsequently to gaining a medical qualification and lay down that the diploma shall not be granted until two years after such qualification. There has been correspondence with various licensing bodies on their interpretation of the new rules. It is noteworthy that the Council recognises for Part I. of the Diploma the courses of lectures and practical instruction given at the Staff College to officers of the Royal Army Medical Corps, and at the Naval Medical School, Greenwich, to medical officers of the Royal Navy. At a meeting of the committee held in May last a communication was received from the Society of Medical Officers of Health giving a considered opinion on the practical training required for the diploma. It was resolved, inter alia, that the committee would keep in mind the suggestions offered and would have regard to them in the interpretation of the rules. It is stated that the Diploma in Hygiene of the University of Cambridge is not recognised by the Council.

MEDICINE AND THE LAW.

The Time-Limit Upheld.

The Court of Appeal has promulgated an important decision upon the limitation of legal liability in the case of a medical practitioner discharging public duties. The Public Authorities Protection Act of 1893 contains, as was illustrated in a recent Edinburgh case,[1] a not unreasonable protection for persons acting in execution of statutory or other public duty. Proceedings do not lie, and are not to be instituted against such persons unless commenced "within six months next after the act, neglect, or default complained of, or, in case of a continuance of injury or damage, within six months next after the ceasing thereof." The wording of the statute is not very happily drafted, and has required legal explanation more than once. It is easy to reckon six months from an act which causes injury or damage. But the phrase "continuance of injury or damage" has been a stumbling-block. The facts on which the decision in the recent case of Freeborn *v.* Leeming is based are briefly these. A man was run over by a motor-car on Sept. 5th, 1923, and was taken into a workhouse infirmary next day. The doctor in charge had no direct contractual obligation towards the patient who was not one of his charges in the ordinary sense; but the law, of course, expects every practitioner to apply reasonably competent skill in the art which he professes. It was alleged that the doctor neglected to make an adequate examination, and that he failed to diagnose a dislocated hip. The plaintiff stayed on in the infirmary till Oct. 15th, and then went home at his own risk. The date is important, because it was the day on which he passed out of that doctor's care. Fresh medical opinion, it was alleged, subsequently diagnosed the dislocation, but found that it was now too late to reduce it; an operation had to be performed, and in consequence the patient has one leg permanently shorter than the other.

Six months and six days after the date on which he left the workhouse infirmary the plaintiff issued his writ, and began his action against the infirmary doctor. Prima facie his action was six days too late. Obviously, if the permanent shortening of his leg was a continuing injury or damage within the meaning of the Act of 1893, he could safely have sued the doctor without time-limit at any moment during the rest of his life. But there was solid legal authority against this view. In Carey *v.* Bermondsey Borough Council (1903) the Court of Appeal decided that the continuance of suffering is not a continuance of injury or damage within the meaning of the Act. Lord Halsbury, who delivered judgment to that effect, had a special gift for common-sense interpretation. Words, he said, must be reasonably interpreted. It was not unreasonable to say that if there was a continuance of an act causing damage, the injured person should have an action at any time within six months of the ceasing of the act complained of. But that was wholly inapplicable to a case where there was no such continuance of the act complained of and where the only suggestion was that, in consequence of the negligent act, the victim was not such a good man as he had been before. The county court before which the recent case was first heard tried hard to find a way round Lord Halsbury's decision. An ingenious argument by the plaintiff's counsel was accepted. The dislocated hip, it was argued, if properly diagnosed originally, would not have been cured, even with proper treatment till, say, eight or ten weeks after the accident. It was not until this prospective date of cure was reached that the plaintiff (being at that moment a still disabled man instead of a now quite cured man) had his full right of legal action. It was at this imaginary but guessable date that the plaintiff's damage arose. If the six months had been reckoned from that date, the plaintiff's action was begun in ample time. Taking this view the county court judge awarded him £1800 damages, but the Divisional Court upset the award on the ground that the action was not begun within the six months. This latter view the Court of Appeal has now confirmed.

The case may be carried to the House of Lords, but any other view than that expressed in the judgment of the Court of Appeal would be disastrous to medical practitioners who hold official positions and would make nonsense of the Act.

Mistaken Identity.

The reissue of Mr. Sully's brief study[2] in the psychology of identification is timely. Police methods were criticised in Major Sheppard's case, and, still more recently, the Lord Chief Justice has commented on the abuse of photographs as a preliminary to identification. The essayist takes the imaginary example of a passenger dashing hurriedly one night into the last up train leaving a local railway station. Jones, the porter, is subsequently asked to identify the man. The newspapers next day report a murder. The wanted man is rumoured to have got away by the last train to London; presently it is said that a young and well-dressed man who travelled by that train has been arrested. Jones attends the identification parade with a memory which blends genuine

---

[1] Gorrie *v.* Smith, The Lancet, Nov. 7th, p. 990.

[2] Mistaken Identity. By Clifford Sully. London: Longmans, Green and Co. 1924. Pp. 15. 6*d.*

(and perhaps inaccurate) recollections with items read or heard. If confronted with the arrested man, Jones may be predisposed to believe that the man he remembers is the man he sees; else why would he be there? Even if photographs have not been displayed beforehand, other forces of suggestion are at work. Though himself smartly dressed, the man may be put up amongst a number of ill-dressed navvies (as was alleged in Stinie Morrison's case). An involuntary self-consciousness may betray the accused man, or some action of his companions may tell a tale. The essay under review makes various proposals. Since it is the first identification that counts (subsequent re-identification being merely formal), Jones might be put on oath to make him more consciously careful; or he might be specially warned of the difference between recognising a person previously seen and spotting a probable criminal. There might even be two or more identification parades, the arrested man being absent from the first or second. These and other observations in Mr. Sully's essay were well worth making. Official complacency has under-estimated the effect of suggestibility. It will be interesting to see (if they are not regarded as confidential) the new regulations which the Home Secretary has undertaken to make upon the subject of identifications.

AMERICAN PUBLIC HEALTH ASSOCIATION:

ANNUAL MEETING.

(FROM OUR OWN CORRESPONDENT.)

THE fifty-fourth annual meeting of the American Public Health Association, held in St. Louis, Mo., was probably the most successful in its history, the registered delegates numbering 911. The epidemic of typhoid fever last winter that was traced to polluted oysters resulted in several papers on

Oyster Sanitation.

These were read to a joint session of the Sections on Public Health Administration, Laboratories, Sanitary Engineering, and Food and Drugs. Drs. Charles Krumwiede and William H. Park, of the New York City laboratories, described observations with oysters that they had contaminated artificially (1) with cultures of typhoid, and (2) with stools from typhoid carriers. *B. typhosus* was found in the liquor and bodies after 49 days storage—the longest period tested, and in excess of the maximum period of storage that is found under actual trade conditions. The changing of oysters to fresh sea-water has a marked effect in diminishing the number of *B. typhosus*; three such changes eliminate 99 per cent. However, even after 18 changes during 24 days *B. typhosus* was isolated. When chlorinated water is used the effect is still more marked. Yet four successive treatments failed to eliminate all *B. typhosus* from the contaminated oysters. The conclusion drawn was that the safeguarding of the oyster-supply must rest on preventing contamination of the beds rather than on treatment of the oysters by existing methods of purification.

Bacteriophage in Surface Waters.

Prof. Lloyd Arnold, of the Loyala University School of Medicine, discussed the significance of bacteriophage in surface waters. Its concentration was found to vary directly with the degree of sewage pollution. Prof. Arnold agreed with other observers that since bacteria are not growing under these conditions there was no autolysis and no speeding-up of the process of purification due to bacteriophage. On the other hand, bacteriophage ingested with an infective dose of typhoid bacilli was liable to cause autolysis of the first cultures, and unless (or until) a resistant strain was developed the cultivation of the typhoid bacilli was prevented. Experimental evidence was presented in support of these conclusions.

In the Section on Epidemiology important papers were read by Prof. E. O. Jordan on influenza, and Dr. Abraham Zingher on the prevention, control, and specific treatment of diphtheria, scarlet fever, and measles.

Perhaps the most important item of business was the creation of a committee on dairy products. Milk control has still many controversial aspects, and it is hoped that a committee representing the sections of Public Health Administration, Sanitary Engineering, Food and Drugs, and Child Hygiene will be able to furnish an important consensus of opinion on some of the disputed doctrines.

A resolution was passed urging the more effective centralisation of federal health work under the direction of a competent trained official. The resolution is to be presented to President Coolidge by a committee of five.

Officers Elected.

As President for the ensuing year the governing council elected Prof. C. E. A. Winslow, of Yale, who was for some time in charge of the medical work of the League of Red Cross Societies at Geneva, Switzerland, and has been indefatigable both in teaching and research in this country. Dr. John A. Amyot, Deputy Minister of Health of the Dominion of Canada, was elected first vice-president. Next year the meeting is to be held in Buffalo, where the strength of the Canadian representation should be even more satisfactory that it has been this year at St. Louis.

BUCHAREST.

(FROM OUR OWN CORRESPONDENT.)

Campaign against Venereal Diseases.

ALTHOUGH State aid for the fight against venereal diseases in the new provinces of Roumania ceased on July 1st of this year, because the Ministry of Finance failed to appropriate the necessary funds, the campaign will continue with the vigour that has characterised the work during the last three years. As the Supreme Sanitary Board set aside a considerable sum for this important phase of public health service for the current biennium, the division of social hygiene will be able to carry on for a time. Owing to the uncertainty of continued financial aid, the eight venereal dispensaries and clinics now operating in Transilvania, Bukovina, and Bessarabia slowed up somewhat during the last few months. An agent of the department is making the round of these clinics with the good news that the usual funds will be forthcoming from the State. The message is proving very stimulating.

Proposed War on Rats in the Roumanian Ports.

A proposed amendment to the building orders, now pending before the Board of Public Sanitation, would make compulsory the rat-proofing of all buildings within 600 ft. of the water-front in all the port cities, such as Braila, Constanza, Galatz, and Giurgiu. According to the estimate of the port sanitary officers there are several million rats in these cities, the property loss caused by them annually runs into millions of lei, and the rats are a menace as carriers of bubonic plague. The new measure provides that no certificate for occupancy of any structure within 200 metres of the water-front shall be issued unless its foundation walls are constructed of concrete or similar material and covered with wire mesh. All windows and other openings must be protected with wire screens, and windows and doors must be arranged to permit fumigation with hydrocyanic gas.

Pregnancy in Tuberculous Women.

At a recent meeting of the Medical Society in Jasy Dr. Rosianu gave a summary of the views held at present on the question of pregnancy in tuberculous women. If pregnancy has taken place the woman should be kept under careful medical observation, and if the tuberculous disease grows worse, abortion should be strongly recommended. During the later months of pregnancy the induction of premature labour does not offer any advantage over labour at full term, and is fraught with risk for a tuberculous patient. Moreover, as a tuberculous mother may give birth to a healthy child with fair chances of good health later on, it would be unfair to sacrifice needlessly the life of an infant. Dr. Rosianu does not believe in making a routine of interrupting the pregnancy, as advocated by Maragliano and Hamburger.

Phototherapy in Rachitis.

Dr. Ramniceanu reports the results of ultra-violet treatment made with special arc lamps in 42 cases of rachitis. The patients ranged from 1 to 7 years of age. Every month comparative rontgenograms of the epiphyses of the right forearm were made on four children. In all cases that could be thus controlled there was an undoubted improvement in the clinical picture; in most cases a complete cure was effected. At first the treatment was applied every second day, but of late he has given daily treatments. He begins with five minutes each to the abdomen and back at one sitting. The time is lengthened by two minutes at each sitting until 15 minutes each is reached. No ill-effects following the treatment were noted. No changes in diet were ordered and no medication was employed. The number of sittings was usually from 40 to 60. The rontgenograms established the fact that the bones were becoming harder and firmer. The initial softness of the bones should, of course, be taken advantage of to straighten curvatures and correct deformities, while irradiation is continued, so that when the bones become firm they may be in the corrected position.

Gastro-intestinal Disorders in Albania.

There is an alarming increase of gastro-intestinal disorders in Albania; thousands of working men are unemployed, and are compelled to live on a semi-starvation diet. The sanitary conditions of the bakeries are very unsatisfactory; the bread is bitter and made of inferior flour (chiefly maize) in a primitive manner. Another great source of gastro-intestinal disease is the enormous consumption of decayed vegetables, raw or in a half-cooked condition, and dried fruit, chiefly prunes, in partly decomposed state. The cases of gastro-intestinal disorders are for the most part mild, and recovery takes place without complication; only a few fatal cases have as yet been reported.

Donations and Bequests.—The Liverpool Hospital Sunday Fund this year—the fifty-fifth annual collection—amounted to £7752, being £413 more than the amount subscribed last year.—Princess Beatrice has given £105 to start a £15,000 fund for the renovation of the Royal Isle of Wight County Hospital.—Lady Violet Charlotte Julia Maria Watt, Brighton, left property of the value of £17,825. She left £500 each to the Royal Sussex County Hospital, the Alexandra Hospital for Sick Children, Brighton, the Throat and Ear Hospital, the Hospital for Women, Brighton, the Brighton, Hove, and Preston Dispensary, and £250 to Our Dumb Friends' League, and the residue of the property to her executor for such charitable purposes as he may select. —Mr. David Levy, Brixton, left £16,440. After various bequests he left the residue of the property in trust for his wife for life, and then to King Edward's Hospital Fund for London.—An anonymous donor has given £1000 to Crickhowell Memorial Hospital in commemoration of the visit of the Prince of Wales to Glenark Park, Crickhowell.—Mr. John David Miller, Clifton, Bristol, left £500 each to the Bristol Royal Infirmary and the Bristol General Hospital; £250 to Muller's Orphanages, Ashley Down, Bristol; and £150 each to the Bristol Eye Hospital and the Bristol Hospital for Sick Women and Children.

Correspondence.

"Audi alteram partem."

REPRESENTATION OF MEMBERS ON THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

To the Editor of The Lancet.

Sir,—I gather from the President's remarks at the annual meeting of Fellows and Members, held last week, that the Council of the College is to consider further the question of the representation of members on that body. Since that meeting, I have had before me the information regarding the history of this movement, which was put before the President by a deputation of the Society of Members of the College, and I am astounded to find that the right of representation on the College Council originally existed and was taken away from them, as I understand, surreptitiously and illegally, about half a century ago by the then Fellows.

In these circumstances, it is amazing to think that a body of gentlemen of the calibre of those who form the Council, and among whom, at the present time, I am proud to reckon many friends, could refuse to rectify such a gross injustice to the Members of the College, and one which has continued for over such a long period. Although the Society of Members have been the movers in this matter, the responsibility of the Council exists to far beyond their limited membership. Though I am not a member of this Society, I consider that the Council owes a sacred duty to the body corporate of the College to put this matter right. I had the pleasure of hearing Dr. Haden Guest's address, and I think he made out a case which is beyond dispute. The Council now has the opportunity of rectifying the injustice of its predecessors, and I hope that it will proceed to do so quickly.

Should the Council of the College refuse to do this, it seems to me that the logical course for it to pursue, in seeking a new charter, would be to have the members of the College degraded into a body of licentiates, such as exists in the sister college. I do not suppose for a moment that it would be allowed to do that; but to my mind it is the only logical alternative to the retention of the status of membership. I am quite sure that it would be to the advantage of the College and, indirectly, of the public, whom it serves, that it should agree to receive one or two members on its Governing Board. It appears to me to be very unfair that I, as a member of a university, should have a voice in the government of that university and a Parliamentary vote for its Member, while thousands of members of the College should not even have one representative on its College Council. I am, Sir, yours faithfully,

Lewis G. Glover, M.D., M.R.C.S., L.R.C.P.

Nov. 26th, 1925.

*** The subject is dealt with in another column. —Ed. L.

THE TROPHOBLASTIC HYPOTHESIS OF CANCER.

To the Editor of The Lancet.

Sir,—It is surely unreasonable of anyone to expect to find historical references to other theories in an address summarising the work of many years. After what Dr. Murray has written, however, concerning my presumed want of knowledge on this matter, justice demands that I comment severely upon his own ignorance of the literature in respect of a previous publication of mine in The Lancet [1] in which, when dealing with the importance of chorion epithelioma in relation to certain aspects of the ætiology of cancer, I acknowledged that, though I had arrived at a similar conclusion independently, I subsequently discovered that I had been anticipated in this matter by Dr. Adami in a discussion on Cancer at the Chelsea Clinical Society in March, 1902[2]—that is, prior to Dr. John Beard's publication[3] to which Dr. Murray has referred. Of Dr. Adami's paper Dr. Murray presumably is also ignorant.

---

[1] The Lancet, 1924, i., 267.

We owe to Marchand and a group of German workers, and not to Beard, the demonstration that chorion epithelioma is a malignant growth sui generis derived from the embryonic trophoblast. But all this is common knowledge, and it is hardly likely that anyone to-day would claim it as original! If Dr. Murray will read, and read carefully, my address he will see that I state very definitely that our working hypothesis is based on known facts, as it should be. The difference between our views and Beard's confused ideas is striking. Beard regarded the fertilised ovum as producing an alternate asexual generation; on it is developed an individual, which for clearness we may term the blastula. From this there was now unfolded and developed the sexual individual—the embryo. His theory was that the asexual part (the chorion) might continue to exist after the sexual product had been destroyed or removed, and from this it followed that secondary growths in the lungs and elsewhere were to be considered asexual generations. Beard sums up his hypothesis in the last paragraph of the paper mentioned in the following words:—

> Granted the facts of the origin, migrations, and history of the germ-cells of vertebrates, and assuming the course of the life-cycle to be that previously indicated, by hypothesis cancer is derived from vagrant primary germ-cells, which, instead of forming a more or less complete embryo or embryoma, skip this and give rise to a larva or phorozoon of indefinite unrestricted powers of growth.

Adami and I have had no such ideas. Our conception has been that the chorionic epithelium grows and penetrates the uterine tissue in performance of a special function—that is, to secure nourishment for itself and the growing embryo; that through it foodstuffs are absorbed from the maternal blood, and the other interchanges are made; that if the fœtus die or become aborted this normal function ceases to be required, and that now, to employ Adami's expression, the habit of work being interrupted, the habit of growth may continue, or as I expressed it, the embryonic restraint being removed the chorionic epithelium may multiply and become excessively malignant. This is totally different from John Beard's hypothesis, which I agree could not be fruitful.

With this statement, which should have been entirely unnecessary, I must leave your readers to judge Dr. Murray's letter. Speaking not only for myself but also for the whole staff of the Liverpool Cancer Research Fund, I wish to say that we most cordially invite criticism of our work on its scientific merits. We do not want opinions, pious or impious; we, like all other honest workers, want the truth.

I am, Sir, yours faithfully,

Liverpool, Nov. 30th, 1925. W. BLAIR BELL.

PS.—Will you allow me to say that the following paragraph was omitted by accident from my Toronto address in THE LANCET of Nov. 14th, but will appear in the reprints. It should follow the first paragraph in the left-hand column on p. 1005. Those interested will be able to read it into the rest of the argument:—

"Here it seems proper to call attention to a point of interest that affords considerable support to the explanations I have given of certain pathological phenomena; this obvious point appears to have escaped description, and even notice, at the hands of pathologists—at least, I am not aware of any statement on the matter. It is this: chorion epithelioma—the most malignant of malignant diseases—is not a dedifferentiated growth as is every other malignant neoplasm; it is a simple hyperplasia of the chorionic epithelial elements. Dedifferentiation cannot occur for the chorionic epithelium is normally malignant, and is itself the ancestral type."

PROPHYLAXIS OF THE COMMON COLD.

To the Editor of THE LANCET.

SIR,—I have read Dr. Simey's address with great interest. I would like to put forward the suggestion that a common source of infection is the dangerous practice of compelling adolescents to spend an hour or more in all weathers watching matches. The idea that it is disloyal to the school not to appear to enjoy doing so compels many boys and girls to stand on wet ground in cold winds, thus lowering their vitality and resistance to infection. It is not necessary to go back to the classic experiment which produced anthrax in fowls to realise that it must be harmful in human beings. Would it be possible for medical officers of schools to arrange that only those who desire to watch matches should do so, and for the rest of the school to be occupied in keeping themselves warm, during the winter months, at any rate?

I am, Sir, yours faithfully,

STELLA CHURCHILL.

Chiswick, W., Nov. 24th, 1925.

MALARIA AS A THERAPEUTIC AGENT.

To the Editor of THE LANCET.

SIR,—In connexion with the malaria treatment of general paralysis, it is interesting to learn from a recent article by Dr. Cabanès[1] that in the Middle Ages it was believed that quartan ague cured epilepsy. Dr. Cabanès quotes Louis XI. as begging the Prior of Notre-Dame des Salles, at Bourges, to pray "incessamment Dieu et Notre-Dame des Salles pour moy, à ce que leur plaisir soit de m'envoyer la fièvre quarte, car j'ay une maladie dont les physiciens disent que je ne puis être guéry sans l'avoir." According to Dr. Cabanès, Louis XI. was an epileptic. It appears he also suffered from leprosy, and the fact throws light on the king's strange behaviour. Notwithstanding such drawbacks, he yet managed to weld a disunited country into a kingdom.

I am, Sir, yours faithfully,

London, W., Nov. 29th, 1925. GEORGE PERNET.

PRECANCEROUS STATES.

To the Editor of THE LANCET.

SIR,—My experience of tropical granulomata in Calcutta may throw light, however slight, on "precancerous" states in general. Tropical granulomata are frequently subjected to irritation to such degrees that it is remarkable they do not undergo malignant changes more often than they do. The histological changes observed during the transition of granulomata to malignancy are interesting. There is a varying degree of leucocytic infiltration with a relative preponderance of lymphocytes. This may be due to irritation caused by a specific virus or some changes produced in the invading epithelium. The epithelial cells proliferate and extend both in the longitudinal and vertical planes in the granulation tissue, its proliferation towards the periphery being at first slow. Side by side, there is connective tissue reaction. The perilymphatic and endolymphatic distribution of cells, the epithelial proliferation and invasion and cellular reaction vary according to the type of granuloma, the irritation, and the stage of transformation. In a few cases in which a malignantly transformed granuloma tends to revert to non-malignancy, the connective tissue proliferation seems to result in fibrosis which pervade the growth, the rate and extent of epithelial proliferation become reduced and the cells themselves become more and more normal in character.

I am, Sir, yours faithfully,

K. K. CHATTERJI, F.R.C.S.I.

Southwell-gardens, London, S.W., Nov. 30th, 1925.

---

[1] Mercure de France, May 15th, 1925, p. 197.

POISONS IN THE HOME.

To the Editor of THE LANCET.

SIR,—In reference to the useful annotation with this title which appeared in your issue of Nov. 7th may I ask on what grounds it is stated that many essential oils possessing extremely high carbolic acid coefficients are of relatively small toxicity to human beings? As examples, the writer mentions the oils of origanum and of thyme. I am aware that both of these have high carbolic acid coefficients, but where can I find the evidence that they are less poisonous than the higher homologues of phenol?

I am, Sir, yours faithfully,
HENRY KENWOOD,
Nov. 28th, 1925. M.O.H., Stoke Newington.

⁂ The relatively low toxicity of essential oils may be deduced partly from such direct evidence as that the B.P. gives the dose of sandal-wood oil as 0·3–1·8 g., and the U.S. Dispensatory that of thyme oil as 0·2–0·3 g., compared with phenol, 0·06–0·2 g., and partly from the absence of any records of accidental poisoning.—ED. L.

A DISCLAIMER.

To the Editor of THE LANCET.

SIR,—My attention has been called to the issuing of a leaflet announcing a lecture which I was recently invited to give to the members of the Young Men's Christian Association at their hall in Aldersgate-street. On hearing of it I at once telephoned to the secretary that no further distribution should take place. I need hardly say it was issued without my knowledge.

I am, Sir, yours faithfully,
JAMES DUNDAS-GRANT.
London, W., November, 1925.

POLYCYTHÆMIA RUBRA RELIEVED BY X RAY TREATMENT.

To the Editor of THE LANCET.

SIR,—The case described by Dr. S. W. Patterson in THE LANCET for Nov. 28th (p. 1112) is of especial interest both on account of the question of diagnosis and on account of the good result obtained by treatment. A good result of nine months' duration, like that described, seems to me almost incompatible with a diagnosis of true *splenomegalic* polycythæmia rubra, that is to say, the "Vaquez-Osler syndrome," or "erythræmia." I had the opportunity of seeing the patient twice myself before Dr. Patterson saw her and regarded the case as one of "hypertonia polycythæmica," such as those to which F. Geisböck drew attention in 1904, and as I have explained,[1] I believe that such cases are examples of secondary polycythæmia, connected in some way with the high blood pressure of early stages of granular kidney, or with primary hyperpiesia without definite signs of organic renal disease. On both occasions when I saw the patient the spleen could not be felt, and Dr. Patterson admits it was only just palpable when he first saw the case and soon was not palpable at all. Moreover, a high systolic blood pressure of 170–204 mm. Hg has scarcely ever been made out in a true case of splenomegalic polycythæmia. I have paid especial attention to this, as in 1904, with Dr. J. H. Watson,[2] I made out experimentally with the blood of horses that the so-called blood-viscosity (quite distinct from the *true* viscosity of the blood-plasma or blood-serum) depended almost entirely on the richness in erythrocytes. Since then I have been forced to admit that in splenomegalic polycythæmia there must be some compensatory dilatation of the capillaries which prevents the blood pressure rising[3]; indeed, in many typical cases with an erythrocyte count of about 10 millions to the cubic centimetre of blood, the brachial systolic blood pressure is only about 120–130 mm. Hg.

On the other hand, the syndrome "hypertonia polycythæmica" may, I believe, represent merely a phase or episode in the course of a case of high blood pressure, the polycythæmia disappearing after a time, though the high blood pressure persists or increases. The point on which Dr. Patterson is to be especially congratulated, seems to me that the high blood pressure in his case practically disappeared *as well as the polycythæmia*. I shall certainly endeavour to have similar X ray treatment cautiously tried in cases of hyperpiesia, at all events, in cases associated with polycythæmia. Amongst the Hebrews from the East End of London that come as out-patients or in-patients to the German Hospital are many typical examples of hyperpiesia.

I am, Sir, yours faithfully,
London, W., Nov. 30th, 1925. F. PARKES WEBER.

NASAL LAVAGE AND MIDDLE-EAR INFLAMMATION.

To the Editor of THE LANCET.

SIR,—I hope that Mr. Arthur Cheatle's timely communication (THE LANCET, Nov. 28th, p. 1140) upon the dangers of indiscriminate nasal lavage will be assimilated both by the Ministry of Health and by practitioners generally. May I suggest that the employment of a suitable antiseptic powder as a "snuff" is at least harmless to the ears, and is efficacious in relieving obstruction in any case which does not require surgical interference. I am convinced from experience that the use of the fluid nasal douche results in a noticeable increase in secretion and in the progress to a chronic hypertrophic condition, especially so in the recurrent polypoid growths of everyday practice. Moreover, the treatment by a "snuff" is very conveniently carried out, and in the case of children it certainly helps in the teaching of correct nasal breathing.

I am, Sir, yours faithfully,
Manchester, Dec. 1st, 1925. WILLIAM WILSON.

OPERATIONS ON GERM CARRIERS.

To the Editor of THE LANCET.

SIR,—Something more might have been said in your leading article last week in regard to the proposal to render germ-carriers non-infectious by operation. There are two points wherein the case of a healthy carrier treated under compulsion or under strong moral pressure would differ from the normal case. When a practitioner operates ordinarily, the law gives him protection (except in the case of gross carelessness, ignorance, or inattention), first, because he is endeavouring to improve or conserve the bodily health of his patient; and, secondly, because the patient's consent has either been expressly given or can at any rate be tacitly implied. Operation upon a healthy carrier would be not so much for the improvement or conservation of his health as for the safety of the health of others. And if the operation were conducted as a statutory duty rather than at the express or implied invitation of the patient, there would be an absence of the professional protection which the tacit or explicit consent of the patient ordinarily creates. Distant though it may be, this is an aspect of the matter which should be borne in mind.

I am, Sir, yours faithfully,
LEX

Obituary.

RICHARD DENISON PEDLEY, F.R.C.S. EDIN., M.R.C.S. ENG., L.D.S.

Mr. Richard Denison Pedley, consulting dental surgeon to the Evelina Hospital for Children and to Dr. Barnardo's Homes, died on Nov. 25th at India House, Addiscombe, at the age of 68. He received his professional training at St. Thomas's Hospital, where he became demonstrator in dental surgery, and at the Dental Hospital where he later was assistant dental surgeon. In 1883 he obtained the M.R.C.S. Eng., and the following year the Licence in Dental Surgery. In 1887 he became F.R.C.S. Edin. by examination, and eight years later published his first book with the title of the "Diseases of Children's Teeth: their Prevention and Treatment." At this time he was dental surgeon to the Evelina Hospital for Sick Children, and the experience which he had gained by devoting his whole time to the subject of his specialty was embodied in the treatise and made available for medical practitioners and students. This supplied a want of the time, for it frequently happened that the doctor was called upon to take the place of a dentist without having had the necessary training. In 1898 and 1908, respectively, Mr. Pedley published "Hygiene of the Mouth," and jointly with Mr. F. Harrison, "Our Teeth," two books of a more general character. In 1904 he wrote for THE LANCET (1904, ii., 1207) an article designed to direct attention to the neglect by the medical profession of dental disease, predicting that public opinion among other outside forces would compel attention to be paid to this matter. His suggested remedy for this neglect was that medical students should be warned that in all final examinations an occasional question would be put on the causation, effects, and treatment of dental caries. If this were done, he said, "In ten years' time the 13,000 general practitioners who have registered will be well aware of the prevalence of dental disease, which, if they cannot cure, they will do much to prevent." We have travelled far since Mr. Pedley wrote these words. It must have been a gratification to him to have lived to a time when practitioners do attach importance to dental disease and to feel that his influence may have contributed largely to this change of attitude. Mr. Pedley was a past President of the School Dentists Society, a Fellow of the Royal Society of Medicine, and a Fellow of the Royal Society of Arts.

ELIJAH BAXTER FORMAN, M.D. BRUX., M.R.C.P. LOND., J.P.

Dr. E. B. Forman, who died on Nov. 25th at his residence, Chalfont St. Giles, had reached the advanced age of 86 years. He was for 20 years a member of the London County Council, representing North Hackney and South Kensington, and later becoming an alderman. Among the offices he had filled were the vice-chairmanship of the Education Committee and the chairmanship of the Public Health and Midwives Committees; in 1906 he was deputy chairman of the Council.

The son of Mr. E. Forman, of Derby, he was educated privately, entering Guy's Hospital where he gained scholarships in medicine and wrote a prize essay on Bright's disease. In 1863 he qualified with the M.R.C.S. Eng. and L.R.C.P. Lond., and after graduating at Brussels in 1877 obtained the M.R.C.P. in 1889. He started practice in Stoke Newington, moving after a few years to South Kensington, where his whole active professional life was spent. He took an interest from the first in municipal hygiene and had prevision of medical progress in the direction of prevention as distinct from cure. An address on "Medical London," which he delivered at the South Place Institute in 1899, and published in our columns, showed a wide grasp of Poor-law and sanitary administration. Everyone, he said, is concerned in a movement the object of which is to prevent disease and prolong life. He advocated simplification of health administration, and the adoption of a uniform coherent system which only centralisation could bring about. Happily he lived long enough to see the realisation of his ideal in the Ministry of Health.

JOHN ELSDALE MOLSON, M.D., B.CH. CAMB.

THE death took place on Nov. 28th at Goring Hall, Worthing, of John Elsdale Molson, who for some six years represented the Gainsborough division of Lincolnshire in the House of Commons. The son of Samuel Elsdale Molson, he was born on August 6th, 1863, at Montreal, and received his early education in England at Cheltenham College, afterwards entering Cambridge University and becoming a student at Middlesex Hospital Medical School. In 1889 he qualified with the L.S.A., and in the following year took the Conjoint diplomas of the Royal Colleges. After holding a house appointment at Middlesex Hospital, in 1891 he graduated in medicine and surgery at Cambridge University and proceeded to the M.D. degree four years later. While in practice at Chelmsford he was medical adviser to the Convent of the Holy Sepulchre. Later as Surgeon-Major in the 4th Batt. of the Royal Sussex Territorial Regiment he served during the war both in this country and in Egypt, and he entered Parliament in 1918. After retiring from practice he was a justice of the peace for West Sussex.

Dr. Molson married Mary, daughter of Dr. A. E. Leeson, by whom he had three sons and one daughter.

CHARLES EWBANK LANSDOWN, M.R.C.S. ENG., L.R.C.P. LOND.

Dr. Charles Ewbank Lansdown, one of the best-known medical practitioners in the Midlands, passed away with tragic suddenness on Nov. 24th at Cheltenham. The day before his death he attended his patients as usual and seemed in the best of health. Early on the day of his death he complained of pain, and suddenly fell down and expired. A native of Plymouth, he was a student at St. Mary's Hospital, London, and after qualifying in 1891 he was senior resident medical officer of the London Lock Hospital, honorary house surgeon at St. Mary's Hospital, and resident medical officer at Horton Infirmary, Banbury. He settled in Cheltenham and took over the practice of his deceased half-brother. He was surgeon to the Children's Hospital in Cheltenham. He was an enthusiastic Churchman and Freemason. He leaves a widow, a daughter of Dr. Thos. Savage, of Birmingham, one daughter, and two sons, to whom we extend our sympathy.

THE LATE DR. J. F. S. HAY.—A New Zealand correspondent states that the funeral of Dr. Joseph Frank Strong Hay, M.B., C.M. Aberd., formerly Inspector-General of Mental Hospitals in New Zealand, whose death was announced in THE LANCET of Sept. 19th (p. 586), took place in St. Paul's Pro-Cathedral, Wellington, where there was a large attendance of representatives from all sections of the community. Dr. Hay was born in Lucknow, India, and graduated in medicine at Aberdeen University. After some experience of mental work in Scotland he went to New Zealand in 1897, and on the death of Dr. Duncan McGregor in 1907 he was appointed Inspector-General of Mental Hospitals. In 1923 he married Mary Stuart, daughter of the late Right Hon. R. J. Seddon.

MANCHESTER EAR HOSPITAL.—This hospital draws its patients from an extraordinarily wide area, even from very distant towns, but the financial support from many of these, areas comprising 224 towns, is far from adequate and the financial year finishes with an adverse bank balance. During the past year there were 5580 outdoor patients and 525 in-patients. The number of operations was 995. There is a waiting-list of over 900 patients.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdr. (retd.) E. D. Rutherford to be Surg. Capt. (retd.).

ROYAL ARMY MEDICAL CORPS.

Capt. J. A. Nicholson retires, receiving a gratuity.

TERRITORIAL ARMY.

Capts. F. W. Goodbody and J. B. Foubister, having attained the age limit, are retired and retain their rank.

Capt. J. McCulloch (late R.A.M.C.) to be Capt.

Capt. J. W. Macfarlane resigns his commn. and retains his rank.

ROYAL AIR FORCE.

H. I. Clapperton (temp. Lt., Dental Surgeon, General List, Army) is granted a temporary commission as a Flying Officer on attachment to the R.A.F.

INDIA AND THE INDIAN MEDICAL SERVICE.

The King has approved the relinquishment of their temporary commissions by Capts. Manchar Lal Bhagat and Keshav Ganesh Mohile, who are permitted to retain the rank of Capt.

On return from leave the following officers are posted as indicated : Lt.-Col. R. F. Baird, Civil Surgeon, Allahabad ; Lt.-Col. E. C. Hepper, Civil Surgeon, Bareilly; Lt.-Col. H. Ross (late Secretary, Indian Red Cross Society), Civil Surgeon, Aligarh ; Lt.-Col. C. A. Sprawson, Principal and Professor of Medicine, King George's Medical College, University of Lucknow, in relief of Maj. G. T. Burke, who has been appointed Civil Surgeon, Saharanpur ; and Maj. P. B. Mills, Civil Surgeon, Shahjahonpur. Lt.-Col. H. P. Cook has been transferred as Civil Surgeon from Allahabad to Fyzabad, and Maj. R. S. Townsend, Civil Surgeon, from Bareilly to Gorakpur. Maj. C. G. Howlett, Civil Surgeon of Champaran, has been granted leave.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, NOV. 25TH.

Milk and Dairies Regulations.

Mr. BARNES asked the Minister of Health whether, having regard to the fact that the Milk and Dairies Act of 1915 had been in operation since Sept. 1st last, he was now able to state the date on which the regulations to be operated under this Act would be published ; and whether in view of the scope of the sections of the Act under which it was proposed to issue regulations, he would arrange for a discussion in the House before putting the regulations into operation.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied : My right hon. friend is at present consulting the associations of local authorities with regard to a draft Milk and Dairies Order which has been prepared under the Act of 1915 and he hopes that the draft will be ready for publication about the end of the year. When the Order has been made it will be laid before the House and an address may be presented to His Majesty praying that the Order be annulled. A discussion could therefore take place on the Order on a motion for such an address.

Deaths from Lead Poisoning.

Mr. DUCKWORTH asked the Home Secretary if he was aware of the statements that deaths from lead poisoning were on the increase among lead workers in the pottery trade, and that according to the latest statistics potters between the ages of 35 and 45 had the highest death-rate in Great Britain ; and whether he had any information as to the effectiveness or otherwise of the new lead and dust regulations.—Mr. G. LOCKER-LAMPSON (Under Secretary for Home Affairs) replied : There has been a small increase during the last few years in the deaths from lead poisoning in the pottery trade, but this cannot be taken as any indication of the present conditions. The records show that in the great majority of cases the deceased had been employed in the industry for many years before the Regulations of 1913 came into force. There can be no doubt, I think, if one looks at the total number of cases, that the 1913 Regulations have been effective. Whereas during the six years 1907–1912 the average number of cases was 90, the average for the last six years 1919–1924 was just under 36. It is significant also that in the fatal cases there has been a substantial rise in the average age of the deceased. The statement that potters between the ages of 35 and 45 have the highest death-rate in Great Britain is, I believe, incorrect.

THURSDAY, NOV. 26TH.

Danger to School-children.

Mr. SCURR asked the Home Secretary whether his attention had been drawn to the danger to the public, especially children, of Vallance-road, Whitechapel, particularly where a school, a feeding centre, and a hospital converge ; and whether he would take steps to arrange for better regulation of the heavy traffic by the police, especially when the children were going to and from the school and the feeding centre.—Mr. LOCKER-LAMPSON replied : I am informed by the Commissioner of Police that the traffic in this street, as elsewhere, has greatly increased in recent years. Arrangements are made to secure that, as far as possible, police officers shall be on duty to supervise dangerous crossings in the vicinity of schools when children are entering or leaving, but owing to the large number of schools it is not always possible to spare constables for this purpose, having regard to the other duties of the police. In a densely populated neighbourhood where there are numerous children, and very few places where they can play, except in the streets, it is impossible for the police to prevent accidents occurring, and it does not appear that the posting of a constable at the spot indicated would have prevented such accidents as have unfortunately occurred of late.

The Causes of Epithelioma.

Mr. ROBINSON asked the Home Secretary whether the Departmental Committee on the association of the occupation of the mule minder in the cotton trade with epithelioma had yet reported ; and whether any action was proposed to minimise the incidence of this disease and protect the workers. —Mr. LOCKER-LAMPSON replied : The committee have not yet reported, but I am informed by the chairman that they hope to do so early in the New Year. As regards the latter part of the question, I cannot anticipate the report, but any recommendations of the committee will be taken into immediate consideration.

Deaths from Insect Bites.

Mr. HERBERT WILLIAMS asked the Minister of Health the number of deaths from insect bites in this country during the six months ending Sept. 30th this year, and also the corresponding figures for last year.—Mr. N. CHAMBERLAIN replied : There were nine deaths from insect bites in the six months ending on Sept. 30th, 1924. The corresponding figure for this year is not yet finally ascertainable.

Voluntary Hospitals Report.

Major GLYN asked the Minister of Health whether he had considered the Report of the Voluntary Hospitals Commission ; and whether it was proposed to provide public funds for hospital extension on the lines recommended. —Mr. N. CHAMBERLAIN replied : Yes, Sir. While I fully appreciate the strength of the case of additional hospital beds I regret that in the present urgent need for public economy I could not find myself able to recommend the provision of public funds to assist even in so laudable an object.

Sanitation in Kentish Hopfields.

Colonel DAY asked the Minister of Health if he was aware of the confusion and consequent suffering of hop-pickers in Kent during the recent hopping season ; and would he consider legislation on the lines of the Factory Acts in order to compel owners of hopfields to provide the accommodation required by modern ideas of humanity.—Mr. BRIANT asked the Minister of Health if he was aware that the sanitary condition of many of the hopfields during last season was deplorable ; what steps his department was taking to obtain a permanent improvement in the general conditions ; and would he appoint women inspectors to be on duty next season during the whole of the time that hop-picking continues. Mr. Briant also asked the Minister of Health if inspectors from his department had visited the hopfields during the past season ; and, if so, if the report made could be issued for the information of the House.—Mr. N. CHAMBERLAIN replied : I am aware that the conditions in many camps in the Kent and Sussex hopfields are unsatisfactory, and my department is working in close coöperation with the Ministry of Agriculture and Fisheries with a view to securing improvement. The administration of the law and by-laws relating to this matter is a duty devolving in the first instance on the local authorities, and their efforts, supported by local voluntary workers, have already effected a noteworthy improvement, but I have in preparation new model by-laws which the local authorities will presently be asked to adopt. In the last two years numerous visits have been made by inspectors, both of my department and that of my right hon. friend, including a lady inspector of the Ministry of Agriculture, and I propose to circulate among the local authorities concerned a report recently prepared by one of my medical officers dealing with those hopfields in Kent and Sussex which have been inspected. I shall be happy to send a copy to the hon. Members.

Poor-law Reform.

Mr. **GEOFFREY PETO** asked the Minister of Health whether he would issue to Members the outline of his proposals on the subject of Poor-law reform, which had already been issued to the County Councils' Association.—Sir **JOHN MARRIOTT** asked the Minister of Health whether, as his provisional suggestions or proposals for the reform of the Poor-law had been confidentially communicated to the Association of Municipal Corporations and one or more similar bodies, he would say whether they had also been communicated to the Association of Poor Law Unions; and, if not, if he would state the ground for discrimination.—Lieut.-Colonel **ACLAND-TROYTE** asked the Minister of Health why, when issuing a statement as to his proposed reform of the Poor-law to certain associations, no copy was sent to the Association of Poor-law Unions; and would he issue copies of the statement to Members of Parliament.—Mr. N. **CHAMBERLAIN** replied: The proposals referred to were preliminary proposals devised as a basis for discussion with the representatives of the local authorities to whom it would be necessary to entrust the powers and duties of boards of guardians on abolition, and I thought that it would probably save time and trouble if I considered the proposals further in the light of such discussion before forwarding them to the Association. I am now advised that some time must elapse before the discussion can take place, and accordingly I propose to send the provisional proposals as they stand to the Association and to certain other bodies interested. In this way the proposals will no doubt become public, and it seems scarcely necessary to issue them specially to Members of Parliament.

Advertisements of Cancer Cures.

Sir **JOHN MARRIOTT** asked the Minister of Health whether he had received representations from responsible quarters urging him to introduce legislation to deal with advertisements for cancer cures; and what action he proposed to take in a matter which was regarded by the medical profession as urgent.—Mr. N. **CHAMBERLAIN** replied: I have not received any recent representations, but the matter was fully discussed in the report of the Select Committee on Patent Medicines. The question raised by my hon. friend shall be carefully considered in connexion with any legislation for the control of the traffic in secret remedies.

Vaccination and Sleepy Sickness.

Mr. **COMPTON** asked the Minister of Health whether he would give instructions to all medical officers receiving notifications of cases of sleepy sickness to inquire whether such cases had at any time undergone vaccination and, in those cases where the operation had been performed, to note the date and result of the last vaccination.—Mr. N. **CHAMBERLAIN** replied: I will consider this suggestion in connexion with other questions relating to sleepy sickness which are at present engaging my attention.

Research into Animal Diseases.

Mr. **FOOT MITCHELL** asked the Comptroller of the Household, as representing the Minister of Agriculture, what steps were being taken by his department at the present time in the direction of research into animal diseases.—Sir H. **BARNSTON** replied: Research into animal diseases in England and Wales is carried on at a number of research institutes and colleges maintained or aided by grants from the Ministry. These include the Institute of Animal Pathology at Cambridge, the Royal Veterinary College, the London School of Hygiene and Tropical Medicine, and the Ministry's Veterinary Laboratory. Advisers in veterinary science are maintained at the University Colleges at Bangor and Cardiff, and at Armstrong College, Newcastle. A special committee had been set up to conduct research into foot-and-mouth disease, and work is being carried on under the direction of this committee at a number of laboratories. The total estimated expenditure on the maintenance of this work in the present financial year is £47,000. In addition grants in aid of capital expenditure totalling £118,650 have recently been sanctioned by the Ministry in respect of the work. Reports on the research organisation set up by the Ministry and on the work of the various bodies concerned will be found in the report on the work of the Intelligence Department of the Ministry for 1921–24 and the First Progress Report of the Foot-and-Mouth Disease Research Committee. These reports are published by and obtainable from H.M. Stationery Office.

MONDAY, NOV. 30TH.

Colonial Medical Director.

Lieut.-Colonel **ANGUS MCDONNELL** asked the Secretary of State for the Colonies whether the Government had come to any decision as to the appointment of a medical director as a permanent member of the Colonial Office staff for the purpose of coördinating medical research work in the different Crown Colonies.—Mr. **AMERY** replied: The matter is still under consideration.

The Spahlinger Serum.

Captain **BOWYER** asked the Comptroller of the Household, as representing the Minister of Agriculture, what steps he was taking to test Mr. Spahlinger's reputed cure for bovine and human tuberculosis, or whether the Ministry was already satisfied as to the efficacy of Mr. Spahlinger's sera.—Sir H. **BARNSTON** replied: The Ministry has not itself made any test of Mr. Spahlinger's serum, or of any other specific of which the basis is kept secret and not submitted to scientific inquiry. It understands, however, that an investigation into bovine tuberculosis is being undertaken by a committee representative of certain agricultural and professional interests in Cheshire, where tests are being conducted with the coöperation of Mr. Spahlinger.

Infant Mortality at Market Drayton.

Sir **CHARLES OMAN** asked the Minister of Health what was the rate of infant mortality per 1000 births for Market Drayton (Salop) for the first three quarters of 1925, or, if these figures were not yet available, for the first half-year of 1925.—Mr. N. **CHAMBERLAIN** replied: In the first two quarters of 1925 there were in the Market Drayton Urban District 52 births and 5 deaths of infants under 1 year of age, equivalent to a rate of 96 per 1000 births. Figures for the third quarter are not yet available.

Deaths from Tuberculosis.

Mr. **GROVES** asked the Minister of Health the number of persons who died in England and Wales from tuberculosis (all forms) during the years 1914 to 1924.—Mr. N. **CHAMBERLAIN** replied: The figures asked for are as follows: year 1914, 50,298 deaths; 1915, 54,295; 1916, 53,858; 1917, 55,934; 1918, 58,073; 1919, 46,312; 1920, 42,545; 1921, 42,678; 1922, 42,777; 1923, 40,788; 1924, 41,103; total, 528,661.

Destruction of Condemned Meat.

Colonel **DAY** asked the Minister of Health whether he was aware that the Eaton Bray Rural District Council, at their meeting on Sept. 12th last, decided to allow the carcass of a cow, deemed to be suffering from tuberculosis, to be boiled; and would he consider legislation with a view to the destruction of all condemned carcasses.—Mr. N. **CHAMBERLAIN** replied: I am aware of the decision of the rural district council, but I have no reason to suppose that the boiled meat was sold for human consumption. Having regard to the economic value of unsound meat for such industrial purposes as soap-boiling or pig or poultry feeding I should not be prepared to introduce legislation requiring the destruction of all condemned carcasses.

Trained Nurses for National Emergency.

Colonel **DAY** asked the Minister of Health whether it was contemplated appealing to hospitals and Poor-law institutions to supply a corps of trained nurses from the trained staff of such hospitals and institutions which could be used in case of national emergency.—Mr. N. **CHAMBERLAIN** replied: No, Sir. Steps are, however, being taken to secure that the additional nursing staff required on mobilisation by the combatant services should be obtained with a minimum of disturbance of the voluntary and Poor-law hospitals.

Arm-to-Arm Vaccination.

Mr. **GROVES** asked the Minister of Health whether he was aware that it was still the practice of many medical practitioners to employ the arm-to-arm method of vaccination in private practice; and whether, in view of the serious risks attending such practice, he would consider the desirability of making representation to the medical profession on the matter.—Mr. N. **CHAMBERLAIN** replied: The answer to the first part of the question is in the negative. My information is that comparatively few medical practitioners now employ this method of vaccination and I scarcely think it necessary to make representations to the medical profession on the matter.

DONCASTER INFIRMARY.—The accommodation at this infirmary is so inadequate that patients have had to be temporarily "bedded-down" in the receiving ward, and two children have had to occupy one cot. An extension is being built which will provide 70 extra beds. This will be the third enlargement in 20 years.

Medical News.

University of Cambridge.—There are at present 464 medical students in the University, of whom 157 are in their first year, which is about 30 more than the second- or third-year men. There are 127 in their second year, 122 in their third year, and 58 in the fourth or later year.

University of London.—At the examination for the Diploma in Psychological Medicine, held recently, the following two candidates passed, with special knowledge of psychiatry: Edward W. Anderson and George Brown.

Royal Commission on Lunacy and Mental Disorder.—The next meetings will take place at 5, Old Palace Yard on Dec. 10th at 2 p.m., and 11th at 10.30 a.m.

Old Epsomian Club.—The annual general meeting of this club will be held on Thursday, Dec. 10th, at 6.30 p.m., at the Trocadero Restaurant. It will be followed by the annual dinner at 7.30 p.m.

Tuberculosis Society.—A meeting of this society will be held at 1, Upper Montague-street, Russell-square, London, on Friday, Dec. 11th, when Dr. Otto May, principal medical officer of the Prudential Assurance Company, will speak on Life Assurance and Tuberculosis.

National Association for the Prevention of Tuberculosis.—Owing to the death of Queen Alexandra the dinner in aid of the National Association for the Prevention of Tuberculosis, which had been arranged for Dec. 9th, has been indefinitely postponed.

West Kent Medico-Chirurgical Society.—A meeting of this society will be held at the Miller General Hospital, Greenwich, S.E., on Friday, Dec. 11th, at 8.45 p.m., when Mr. Wilfred Trotter will deliver the Purvis Oration on the Surgery of Malignant Disease of the Pharynx.

New Health Society.—A luncheon will be given on Friday, Dec. 11th, at 1 p.m., by the Aldwych Club, at the Connaught Rooms, Great Queen-street, London, W.C., to the founders of this society, when Lord Oxford and Asquith, one of the founders, will deliver an address on National Prosperity and the Nation's Health.

Child-Study Society, London.—A meeting of this society will be held at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., on Dec. 10th, at 6 p.m., when Dr. R. Langdon-Down will speak on the Teaching of Shorthand as Part of a General Education. Chairman, Dr. A. F. Tredgold.

Royal Society.—The anniversary meeting was held on Nov. 30th when the officers proposed by the Council (see The Lancet, 1925, ii., 1042) were duly elected. Sir Charles Sherrington, the retiring president, called attention to the receipt last year of a generous anonymous bequest of £10,000 which had been used in the investigation of kala-azar in Northern China by Major Patten and Dr. Hindle. A further bequest from the same source had been received this year, amounting to over £28,000. From the fund accruing to the society in 1921 by the bequest of Miss Foulerton, a further research professor had been appointed in the person of Prof. A. V. Hill.

Fellowship of Medicine and Post-Graduate Medical Association.—Sir Charles Gordon-Watson will lecture for the Fellowship of Medicine on the Prevention and Correction of Deformity in Tuberculous Joints in the Lecture Hall of the Medical Society of London, 11. Chandos-street, W., on Monday, Dec. 7th, at 5.30 p.m. The lecture is free to members of the medical profession.—The Hampstead General Hospital will hold a 4.30 to 6 p.m. course for the convenience of the general practitioner from Dec. 7th to 19th covering all branches of medicine and surgery.—Beginning also on Dec. 7th is a two weeks' afternoon course in Dermatology at the Hospital for Diseases of the Skin, Blackfriars. Instruction will be given in the out-patient department and venereal clinics will be held twice weekly.—The following are the special courses for January: Medicine, Surgery, and the Specialties at the Prince of Wales's General Hospital; Cardiology at the National Hospital for Diseases of the Heart; Diseases of Children at the Queen's Hospital; Infectious Fevers at the North-Eastern Hospital; Neurology at the West End Hospital for Nervous Diseases; and Psychological Medicine at the Bethlem Royal Hospital.—A copy of each syllabus and the Fellowship general course programme will be forwarded on application to the Secretary to the Fellowship of Medicine, 1, Wimpole-street, London, W.C. 1.

Harveian Society of London.—A meeting will be held at the Paddington Town Hall, Paddington Green, London, W., at 8.30 p.m., on Dec. 10th, when a paper on the Relationship of Certain Diseases of Animals to Mankind will be read by Prof. F. Hobday.

Centenarian Life Governor.—Mrs. Raby, of Bath, who recently sent a donation to Charing Cross Hospital on her 106th birthday, has, in recognition, been appointed a life governor of the hospital.

East London Children's Hospital.—Recently Sir Joseph Burn, the general manager and actuary of the Prudential Assurance Company, opened the new pathological laboratory which has been equipped at the expense of the company. The "Prudential" is also endowing six beds. The new electrical department for ultra-violet and X ray treatment was opened at the same time.

Queen Charlotte's Maternity Hospital.—The following post-graduate lectures will be given during January and February, at 5 p.m., at the hospital, Marylebone-road, N.W. Jan. 14th, Mr. A. W. Bourne: Maternal Mortality; 21st, Mr. J. B. Banister: Late Manifestations of Puerperal Sepsis; 28th, Mr. T. B. Davies: Ante-partum Hæmorrhage; Feb. 4th, Mr. L. C. Rivett: Infant Feeding; 11th, Mr. L. G. Phillips: Management of Contracted Pelvis; 18th, Mr. C. S. Lane-Roberts: Ectopic Pregnancy; 28th, Mr. L. H. W. Williams: Acute Abdominal Pain in Pregnancy.

Provision for Infectious Disease in Shropshire. Salop County Council is considering a suggestion by Dr. James Wheatley, the county medical officer, that the best method of making provision for infectious diseases would be the erection of a central hospital. At present there is no provision of this kind in districts with a total population of 146,000. Dr. Wheatley recommends the erection of a hospital, to be provided and managed by the county council, on a site near Hadley belonging to the East Shropshire Joint Hospital Board, where there is already good sewerage and water-supply.

Royal Institute of Public Health. — The Harben lectures will be delivered in the Lecture Theatre of the Institute, 37, Russell-square, London, W.C., by Prof. J. C. G. Ledingham, F.R.S., on Current Problems in Bacteriology and Immunology, and their Bearing on Public Health Effort, as follows: Lect. I.: Some Problems of Natural Immunity and Prophylaxis, Dec. 9th; Lect. II.: The Carrier Problem in Relation to Enteric Fever and Diphtheria, Dec. 10th; Lect. III.: Studies on Variola, Vaccinia, and Avian Molluscum, Dec. 11th, at 5 p.m. on each day. No tickets of admission are required.

An X Ray Victim.—Mr. Reginald G. Blackall, one of the early X ray workers at the London Hospital, who has suffered from X ray dermatitis for many years, died on Nov. 29th at the age of 44 years. He joined the staff of the London Hospital in 1902, at a time when the dangers of X rays to the operator were little realised, and has shared the fate of his colleague Mr. E. Wilson, who died, and Mr. E. Harnack, who lost both arms. Mr. Blackall had both his hands amputated in consequence of carcinoma. He continued to work after he knew of the danger, but was compelled to retire in 1920. Three years later the Carnegie Hero Fund Trustees awarded him an honorary certificate and a grant of £75 a year. Soon after, at a quarterly court of the London Hospital, Lord Knutsford presented him with the framed testimonial of the Hero Fund, and announced an award by the hospital of a pension of £285 a year and of a substantial life insurance for his wife and family.

Society of Medical Officers of Health.—The meeting of this society at the Medical Institute, Newcastle-on-Tyne, will be held on Friday, Dec. 11th, and not on the date previously announced The President, Dr. G. F. Buchan, will be in the chair, and there will be a discussion on Industrial Hygiene from the point of view of: (*a*) Public Health Administration, by Prof. Harold Kerr, M.O.H., Newcastle-on-Tyne; (*b*) The Physician, by Sir Thomas Oliver; (*c*) The Works Director, by Mr. Angus Watson, chairman of Messrs. Angus Watson and Co., Ltd.; (*d*) The Welfare Supervisor, by Mr. B. L. Lelliott, welfare supervisor, Messrs. Sir Jas. Laing and Sons, Ltd., Sunderland. The dinner of the Northern branch will be held at the close of the meeting, and members of other branches are invited to notify Prof. H. Kerr, Town Hall, Newcastle-on-Tyne, if they are able to attend. As branches have often expressed the wish that meetings of the whole society should be held from time to time in the provinces, it is hoped that there will be a large attendance, especially of members from the North of England and Scotland, at the Newcastle meeting.

REOPENING OF GOLDEN-SQUARE HOSPITAL.—Mr. Lionel de Rothschild last week reopened the in-patient department at the Hospital for Diseases of the Throat, Golden-square, which has been closed for two years during rebuilding and extension. The opening ceremony of the extension now reopened was performed by the Dowager Lady Rothschild in 1899. The cost of building and equipment has been £35,000, £4750 of which has been contributed by the King's Fund, in addition to £10,000 when amalgamation with the London Throat Hospital took place. The wards will now accommodate 75 patients, and there are two operating theatres. The late Queen Alexandra sent £50 to the building fund unsolicited.

ROYAL MEDICAL BENEVOLENT FUND OF IRELAND. The annual report of the Royal Medical Benevolent Fund Society of Ireland for the year ending April 30th, 1925, published a few days ago, shows an income from all sources of £2097. In this is included a sum of £422, the amount of income-tax refunded for two years. Of the remainder a sum of £1012 is from dividends and interest. It appears, therefore, omitting small items, that the income directly from subscriptions and donations is some £661. It must be admitted that this is a small sum for the practitioners of the whole of Ireland to contribute. There are some 3000 or more registered medical men practising in Ireland, and an average of 10*s.* each would not be an extravagant estimate of what they might be expected to contribute. In spite of its limited income the Committee appears to have done a great deal of charitable work during the year. Over 80 applications for assistance were granted and only five refused. Among those who were relieved were five medical men, most of the remainder being widows of medical men.

LIVERPOOL'S OPEN-AIR SCHOOL.—A contract for the erection at a cost of £41,690 of an open-air school, the first in Liverpool, has been sanctioned by the Liverpool Education Committee. The school will accommodate 1200 children and will be situated in Walton Hall Avenue. It will include three assembly rooms and domestic science rooms. There will be 12 square feet of floor space for each child over 12 years of age, which meant a considerable increase of cost. The cost worked out at £34 per child, or at least £10 per child higher than in other parts of the country. The school was strongly recommended by the medical profession and is an experiment in open-air teaching.

DAVID LEWIS EPILEPTIC COLONY, MANCHESTER.—At the annual meeting held at Manchester on Nov. 24th Dr. Alan McDougall, the director, emphasised the contrast between the indirect method of cure practised at the colony and the danger of the direct method practised at home. Dr. McDougall said, "Our experience confirms the faith always held at the colonies, but apparently unrecognised still, after 50 years, outside them, that you get better results and at the very least as high a proportion of 'cures,' if, instead of waging a violent war on fits with inadequate weapons, you act as though the fits were only a thing of secondary importance, and make your chief aim the moral and physical welfare of the patient. The direct method of treating epilepsy has been a steadfast failure for 2000 years. It insists on the patient being an invalid, and it produces, unless it is very quickly successful, appalling results. The broader visioning plan adopted at the colonies recognises that human beings who are prevented from being useful to the world degenerate morally; it recognises that the nature of the epileptic patient is ordinary human nature, and it gives him in addition to medicine an outlet for his human activities. A great obstacle to its use is found in the patient's friends." He pointed out that nearly 2000 patients had been admitted to the colony and most of these had benefited in health and happiness. A number had become free from fits and had returned to the ordinary world—a gratifying result, as nearly all the patients had been under treatment several years before admission to the colony. The daily average of colonists during the past year was 368, the highest on record. A new house for 32 children is being erected at a cost of £13,000.

LANCASHIRE AND SPAHLINGER TREATMENT OF TUBERCULOSIS.—On Nov. 27th about 250 representatives of insurance committees, health authorities, approved societies, along with the medical officers of health, tuberculosis officers, drawn from nearly every town and district in Lancashire, attended a meeting at Preston, called by the Lancashire Insurance Committee to hear addresses by medical men who have investigated this treatment. The chairman of the Lancashire Insurance Committee, Mr. J. W. Rawstron, presided. He said no resolution would be submitted, but the individual delegates would be left to convey the impressions they gathered to the bodies they represented, and he sincerely trusted some good would result. In a letter expressing his regret at his inability to be present Sir Alfred Mond wrote that he was heartily in support of the campaign to raise funds to purchase the Spahlinger Institute. Dr. Thomas Watts, M.P. (Withington), said that he and his colleagues who went to Geneva traced a definite 80 per cent. absolute recoveries, which was very different from 11 per 1000 in this country, and the cost would be something like one-fiftieth of our sanatorium treatment. A remarkable fact was that the results were being obtained by partial sera. Dr. Vernon Davies, M.P., said that after investigation the medical M.P.'s came to the conclusion that the results they had seen could only be described as marvellous, while if the records produced were genuine then the cases could only be described as miraculous. Dr. Leonard Williams said if Spahlinger could not go on and finish his work something of the utmost value would be lost to the world. Dr. Harry Jones, president of the Monmouth division of the British Medical Association, said a meeting of 83 doctors in his division had decided in favour of Spahlinger.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, Dec. 8th.

THERAPEUTICS AND PHARMACOLOGY: at 5.30 P.M.
Paper:
Dr. H. Gardiner-Hill: The Feeding of Anterior Lobe Pituitary Extract to Under-Developed Children.

PSYCHIATRY: at 4.30 P.M.
Clinical Meeting at the Bethlem Royal Hospital, S.E.

Thursday, Dec. 10th.

TROPICAL DISEASES AND PARASITOLOGY: at 5.30 P.M.
Papers:
Col. Sir Leonard Rogers: Small-pox and Meteorology in India: Forecasting Epidemics.
Dr. E. A. O. Travers: The Treatment of Leprosy at Kuala Lumpur, Federated Malay States (illustrated with lantern slides and photographs).

EPIDEMIOLOGY AND STATE MEDICINE: Members of this Section are cordially invited to be present.

NEUROLOGY: at 8.30 P.M.
Paper:
Prof. T. Graham Brown: The Physiology of Stepping and its Bearing on the Physiology of the Nerve Centre.

Friday, Dec. 11th.

CLINICAL: at St. Thomas's Hospital, S.E., at 5 P.M.
Demonstration:
Prof. MacLean: The Methods of Determining Renal Efficiency.
Cases:
Cases will be shown illustrating various endocrine disturbances, especially in relation to pituitary diseases.
Dr. Bernard Myers: Case of Splenectomy in a Child for Purpura Hæmorrhagica.

OPHTHALMOLOGY: at 5 P.M.
Clinical Meeting at St. Thomas's Hospital, S.E.

BIOCHEMICAL SOCIETY.
MONDAY, Dec. 7th.—5 P.M. (in the Biochemical Laboratory, Imperial College of Science and Technology, South Kensington). *Communications:*—H. W. Buston and S. B. Schryver: The Isolation of some further Undescribed Products of the Hydrolysis of Proteins. H. Martin and S. B. Schryver: The Action of an Electric Field on Egg Albumin. H. Chick: Sources of Error in the Biological Method of Investigating Fat-Soluble Vitamins. W. V. Thorpe: The Action of Enzymes on the Oxytocic Principle of the Pituitary. R. K. Cannan: Potentiometric Studies in Biological Oxidation Reductions. D. T. Harris: The Action of Light on Blood.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.
MONDAY, Dec. 7th, to SATURDAY, Dec. 12th. Fellowship of Medicine lecture, Medical Society, 11, Chandos-street, W. Monday, 5.30 P.M., Sir Charles Gordon-Watson: The Prevention and Correction of Deformity in Tuberculous Joints (illustrated by lantern slides).—INFANTS HOSPITAL, Vincent-square, S.W. Special Course, Lectures, and Demonstrations every afternoon. Friday, "Round Table" Consultation. Saturday, Visit to Blind Babies' Home, Chorley Wood.—ROYAL WATERLOO HOSPITAL, Waterloo-road, S.E. Special Course in Medicine, Surgery, and Gynæcology. Lectures, Demonstrations, &c., will take place in the Out-Patient Department and Wards.—WEST END HOSPITAL FOR NERVOUS DISEASES, 73, Welbeck-street, W. Lecture-demonstrations, illustrated by cases daily at 5 P.M.—HAMPSTEAD GENERAL HOSPITAL, Haverstock-hill, N.W. 4.30–6 P.M., General Practitioners Course dealing with Medicine, Surgery, and the Specialties.—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars-road, S.E. Afternoon course. Tuesday and Friday, 5.30 P.M., V.D. Clinic. All information as to fees, &c., from the Secretary.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

Thursday, Dec. 10th.—3 P.M., Dr. A. J. Whiting: Physical Diagnosis as illustrated by Cases in the Medical Wards. 4.30 P.M., Mr. N. Fleming: Iritis and Glaucoma.

Daily: In-patient and Out-patient Clinics in General and Special Departments, Operations, &c.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

Tuesday, Dec. 8th.—5 P.M., Dr. W. Griffith: Eczema.
Thursday.—5 P.M. (lecture concluded).

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W.

Thursday, Dec. 10th.—5 P.M., Mr. L. Phillips: The Failed Forceps Case.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.

Friday, Dec. 11th.—4 P.M., Mr. Harold Kisch: Cancer of the Larynx.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.

Wednesday, Dec. 9th.—4 P.M., Mr. Percy Hall: The Rôle of Light in the Prevention and Arrest of Disease.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

Tuesday, Dec. 8th.—4.15 P.M., Mr. J. P. Buckley: The Significance of the Pathological Mesenteric Glands.

Friday.—4.15 P.M., Sir William Milligan: Modern Technique in the Diagnosis and Treatment of Foreign Bodies Impacted in the Food Passages.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.

Tuesday, Dec. 8th.—4 P.M., Principal Sir James Irvine: An address. Prof. Herring to open a discussion.

CHADWICK PUBLIC LECTURES.

Wednesday, Dec. 9th.—5.15 P.M. (in the Barnes Hall, Royal Society of Medicine, 1, Wimpole-street, W.), Dr. A. S. MacNalty: Encephalitis Lethargica (Sleepy Sickness) in England.

Appointments.

Blair, D., M.D. Glasg., has been appointed Superintendent of Prestwich County Mental Hospital by the Lancashire Asylums Board.

McFadzean, J., M.B., Ch.B. Glasg., Assistant Medical Officer, Colney Hatch Asylum.

Odgers, P. N. B., B.M., M.Ch. Oxf., Demonstrator in the Department of Anatomy, University of Oxford.

Williams, J. W., M.R.C.S., L.R.C.P. Lond., Medical Officer of the Penarth District of the Cardiff Union.

Medical Referees under the Workmen's Compensation Act (Additional): Miller, H., M.B., B.Ch. Glasg., and Stockman, R., M.D. Edin., for the Sheriffdom of Lanark.

Vacancies.

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary, Treatment Centre.—Jun. M.O. £500.

Accrington, Victoria Hospital.—H.S. £150.

All Saints' Hospital, 49/57, Vauxhall Bridge-road, S.W.—Res. H.S. At rate of £200.

Birmingham Corporation Infectious Diseases Hospitals.—Sen. Asst. M.O. £500.

Birmingham, Queen's Hospital.—Anæsthetist. Obst. and Ophth. H.S. Also Cas. H.S. All at £70 to £100.

Bombay, Gokuldas Tejpal Hospital.—Hon. P. and two Hon. S.'s.

Bradford Royal Eye and Ear Hospital.—Res. H.S. £120.

Bristol, Southmead Hospital.—Second Asst. M.O. £200.

Cancer Hospital, Fulham-road, S.W.—H.S. At rate of £100.

Chester Royal Infirmary.—H.S. and Asst. H.S. £175 and £125 respectively.

City of London Hospital for Dis. of Heart, &c., Victoria Park, E.—P. to Out-patients.

Colchester, Essex County Hospital.—Asst. H.S. and Reg. £150.

Dreadnought Hospital, Greenwich, S.E.—H.P. and H.S. Each at rate of £110.

Dumfries and Galloway Royal Infirmary.—Sen. and Jun. Res. M.O.'s. At rate of £150 and £100 respectively.

Essex County Council and U.D.C.'s of Grays Thurrock and Tilbury.—M.O.H. for U.D. of Grays Thurrock. £200. M.O.H. for U.D. of Tilbury. £200. And Asst. County M.O. for U.D. of Grays Thurrock, &c. £400.

Fulham Parish.—M.O. of South District. About £250.

Great Yarmouth General Hospital.—H.S. £150.

Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—H.S. and Cas. Surg. O. Each at rate of £100.

Kensington, Fulham, and Chelsea General Hospital, Richmond-road, Earl's Court, S.W.—Jun. Res. M.O. At rate of £75.

London Hospital, E.—Asst. Obstet. and Gynæcological S.

Metropolitan Asylums Board, Mental Hospitals Service.—Jun. Asst. M.O. £500. Also Second Assist M.O. £560.

North Middlesex Hospital, Edmonton, N.—S. in charge of Ear Dept. Three guineas per session.

Nottingham General Hospital.—Res. Cas. O. At rate of £200.

Queen Mary's Hospital for the East End, Stratford, E.—Res. M.O., H.P. Two H.S.'s. Obstet. H.S. H.P. And Cas. O.

Royal Free Hospital, Gray's Inn-road, W.C.—Surg. Reg. £200. Also Med. and Gynæcological Reg. £100.

St. Andrew's Hospital, Dollis Hill, N.W.—Hon. Asst. P. an Hon. Asst. Gynæcologist.

St. Peter's Hospital for Stone, &c., Henrietta-street, Covent-garden, W.C.—Clin. Asst.

Salisbury General Infirmary.—Hon. Ophth. S.

Scarborough Hospital and Dispensary.—Two H.S.'s. Each £126.

Sheffield Royal Infirmary.—Ophth. H.S. £80.

Sheffield Union Hospital.—Res. Asst. M.O.'s. £250.

Stepney Union, St. Peter's Hospital, Vallance-road, Whitechapel, E.—Med. Supt. £900. Also First Asst. M.O. £600. And Second Asst. M.O. £450.

Talgarth, Breconshire, Mid-Wales Counties Mental Hospital.—Asst. M.O. £350.

Tipton Urban District Council.—M.O.H. and Sch. M.O. £800.

Wigan Infirmary.—Third H.S. At rate of £150.

The Chief Inspector of Factories, Home Office, London, S.W., announces vacant appointments for Certifying Factory Surgeons at Kirkwall, Orkney, Stanmore (Middlesex), and Whitehaven (Cumberland).

Births, Marriages, and Deaths.

MARRIAGES.

Joynt—Warnock.—On Oct. 12th, at All Saints' Church, Srinagar, Kashmir, Major Herbert Fletcher Joynt, R.A.M.C., to Florence May, daughter of Mrs. Warnock and late Mr. Warnock, of Wallasey.

O'Byrne—Vigors.—On Nov. 25th, at St. Mary's Church, Hyson Green, Nottingham, Dr. Michael Dermod O'Byrne, to Kate Mary Vigors, widow of Captain C. H. Vigors, M.C., Croix de Guerre.

DEATHS.

Brown.—On Nov. 23rd, at Winckley-square, Preston, Lancashire, Sir Robert Charles Brown, Kt., M.B., F.R.C.P., F.R.C.S., aged 89 years.

Forman.—On Nov. 25th, at "Newmount," Chalfont St. Giles, Buckingham, Elijah Baxter Forman, M.D., J.P., formerly Alderman of the London County Council, aged 86.

Keith.—On Nov. 24th, at a nursing home, Southsea, after operation, Mrs. Caroline Keith, L.R.C.P. and S. No flowers by request.

Leventon.—On Nov. 25th, at Finchley-road, N.W., Julius Leventon, L.D.S. R.C.S.I., aged 50.

Molson.—On Nov. 28th, at Goring Hall, Worthing, suddenly, John Elsdale Molson, M.D., Major, R.A.M.C., T.D., late M.P. for the Gainsborough Division of Lincolnshire, aged 62.

Pedley.—On Nov. 25th, at India House, Addiscombe, Richard Denison Pedley, F.R.C.S. Edin., L.D.S., of Railway Approach, London Bridge, aged 68.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

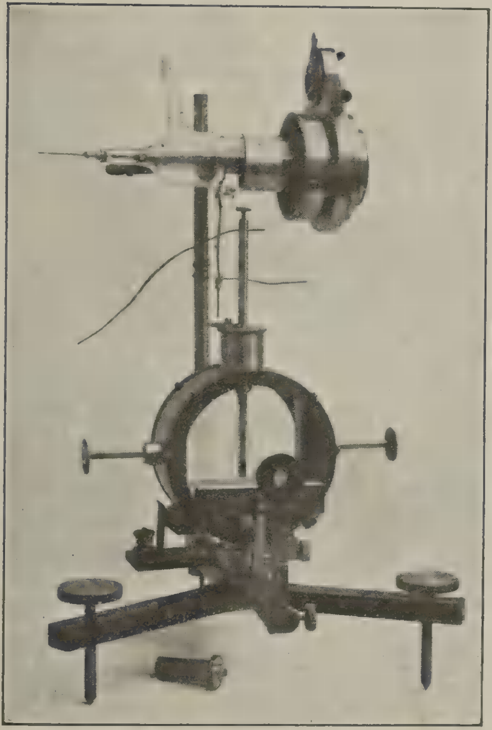
THE PHOTOMETRY OF THERAPEUTIC LAMPS.

AN INSTRUMENT FOR MEASURING ULTRA-VIOLET RADIATION, AND SOME APPLICATIONS OF THERAPEUTIC INTEREST.

BY HARRY D. GRIFFITH, B.A. CAMB.,
ASSISTANT IN NATURAL PHILOSOPHY AND CARNEGIE TEACHING FELLOW IN THE UNIVERSITY OF ABERDEEN;
AND
JOHN S. TAYLOR, M.B., CH. B., D.P.H. ABERD.,
ASSISTANT MEDICAL OFFICER OF HEALTH, CITY OF ABERDEEN.

THE instrument and methods herein described have been developed in order to provide a straightforward means of comparing the intensity of the ultra-violet radiation of lamps used for purposes of artificial sunlight treatment. Somewhat similar instruments have been devised by other investigators[1] [2] for meteorological purposes, but the technique given below is believed to be especially suitable for measuring the radiation of therapeutic lamps.

FIG. 1.



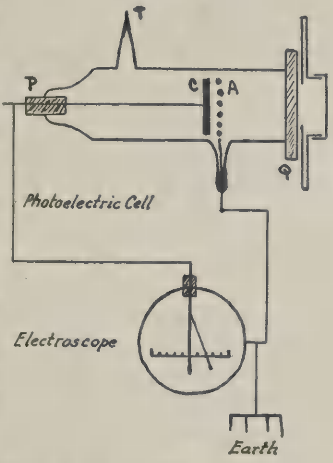
General View of Instrument for measuring Ultra-violet Radiation.

The essential principle of the method is the photo-electric effect discovered by Hertz and Hallwachs, on which a great body of physical research has subsequently been done. The results which emerge are that a metal plate, when illuminated by radiation of wave-length less than a certain critical value, emits electrons, so that if the metal be given a negative charge before illumination this charge is gradually lost during illumination. The "threshold" wave-length depends on the particular metal concerned. The loss of charge can be detected conveniently by means of a gold-leaf electroscope with its leaf connected to the metal plate. If the electroscope and the plate are charged to a negative pressure of, say, 200 volts, relative to the earth, the leaf will diverge. Then on illumination with light of any wave-length less than the threshold wave-length for the metal of the plate, the divergence gradually decreases till all the charge has leaked away. The rate at which the leaf falls is controlled by the rate at which leakage of electricity takes place from the illuminated plate, and this is dependent on the intensity of illumination. Detection of the small leakage current is also possible by means of a galvanometer, but this method is less convenient.

The results obtained tend to be variable unless the active plate (cathode) is protected from chemical change such as oxidation, and it is desirable therefore to enclose the plate in a vessel either evacuated or filled with some indifferent gas, preferably at reduced pressure. A second earthed electrode acting as an anode is provided to give the ejected electrons a definite route out of the cell.

In the application of these facts to the work under consideration, advantage is taken of the photo-electric properties of cadmium, which is insensitive to radiation of wave-length greater than 350 μμ, and of the fact that quartz absorbs waves shorter than about 200 μμ. A photo-electric cell with a cadmium cathode is employed, the cathode being illuminated through a quartz window. In this way a device is obtained actuated only by radiation of wave-length between 350 μμ and 200 μμ—that is, by the region of the spectrum comprising those radiations which are of greatest biological interest. (Figs. 1 and 2.)

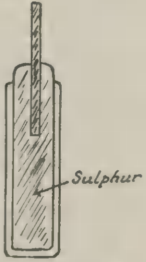
FIG. 2.



The electrodes of the photo-electric cell are mounted in a gas-tight manner in a glass vessel closed at one end with a flat quartz plate Q, through which the active radiation enters the instrument. The cadmium electrode C takes the form of a thin disc of the metal, 22 mm. in diameter, fixed to a copper support. This forms one of the electrodes, and since it is necessary to have it insulated from the glass of the cell in the most rigorous manner, it passes out through the quartz bush P. The anode A is a wide-mesh grid of fine wire placed 2 or 3 mm. from the cathode, and the incident radiation shines through the meshes of this grid on to the cadmium cathode. The seals are made with vacuum waxes of the usual type. After cleaning and fixing the electrodes the cell is evacuated as far as possible (to 0·001 mm. in this case) and tested for leaks over a period of several days. It is then filled with hydrogen or argon to a pressure of about 3 mm. mercury and sealed off at T.

The auxiliary gold-leaf electroscope is one of ordinary type in which the position of the leaf can be read off against a scale. The one used in these experiments has leaves 5 cm. long by 2 mm. wide, and gives a deflection of 12 mm. when the pressure between the leaf and the case is 220 volts. Very rigorous insulation of the support of the leaf is again necessary. Sulphur quartz or amber is required. The "natural leak" of the electroscope and cell together is less than 1 scale division per hour. A diaphragm of adjustable size is mounted in front of the cell and can be set so that the opening is of diameter 16, 8, or 4 mm., allowing the sensitivity to be controlled. It also carries a cap to cover the opening of the diaphragm when the cell is not in use.

FIG. 3.



Charging rod.

The instrument can be charged by touching the rod of the electroscope with the negative wire of the 220-volt direct current-supply, a safety resistance of 50,000 ohms being included to prevent risk of short circuits. Another method is by the charging rod shown in Fig. 3. This consists of a short piece of brass rod with a glass handle, insulation being obtained by means of a sulphur plug. Friction of the rod on the hair of the head electrifies it negatively, leakage of the charge being prevented by the sulphur. On touching the stem of the electroscope with the charged rod the leaves diverge with the necessary negative charge. This is a very convenient and reliable process if the sulphur be kept clean and not handled.

[2] Dorno: Ibid., 1917, xviii., 381.

Experimental Procedure.

When in use the instrument is set up facing the lamp to be studied, and the diaphragm closed to its smallest aperture. A spot of light coming through the diaphragm will appear on the cadmium plate and the cell can be lined up till this is central. With the cap in position and the diaphragm opened to one of the standard sizes, the negative charge is given to the cell. On removing the cap the gold leaf will be seen to fall steadily if active radiation is present. Two suitable points on the scale are chosen within the travel of the gold leaf (in the instrument in use here, division 11 and division 7). A stop-watch is started by the observer when the leaf crosses division 11, and is stopped when it crosses division 7. This is equivalent to measuring the time which the active light takes to cause the leakage of a definite quantity of electricity from the cadmium plate. Several readings are taken as in the examples given later, and the average of these is used for computation.

Results Obtained with Instrument.

At the outset it may be said that when the research was started it was suspected that photo-electric cells of this description would probably deteriorate quickly with use, through "fatigue," contamination of vacuum, and other causes. These doubts have been found to be groundless. It seems that in the measurement of powerful ultra-violet sources to the accuracy aimed at (an error not in excess of 5 per cent.) these bogies of ordinary photo-electric photometry cause no trouble.

Inverse Square Law.

Other things being equal, the cell should give a leak proportional to the total energy of radiation between 350 $\mu\mu$ and 200 $\mu\mu$ entering it—that is to say, using a constant source and keeping the diaphragm to one size, the time of discharge through the standard range should be proportional to the square of the distance from the source. Measurements were made which verified the fact that this relation holds good for cells of the type described, so long as the time of discharge is greater than a certain small value.

Arbitrary Unit of Ultra-violet Intensity.

For the comparison of similar lamps, an arbitrary unit is used which depends on the dimensions of the particular cell used. The unit chosen was a lamp which, when placed 30 in. from the cell, causes the standard leak (division 11 to division 7 on the scale) to take place in nine seconds, the full aperture being used (22 mm.). When a lamp studied, D inches from the cell, discharges the standard amount of electricity in T seconds, the diaphragm opening being A, its power will be given by—

$$P = \frac{1}{100} \times \frac{D^2}{T} \times \left(\frac{22}{A}\right)^2$$

Thus, for the measurement of the power of a lamp, three quantities have to be known—the distance from lamp to cell, the size of aperture used, and a fair average value of the time of discharge.

Constancy of Cell.

The power, calculated by this formula, of a certain quartz-mercury arc as measured on different dates extending over a month was found to be satisfactorily constant: Sept. 27th, 18 units; Oct. 11th, 21 units; Oct. 18th, 23 units; Oct. 20th, 22 units; Oct. 22nd, 22 units. The simplicity of this technique compared with that involved in performing similar measurements with a spectrometer and bolometer or thermopile, or by a photographic method involving measurement of the density of a silver image, is apparent, though admittedly a more rigorous method of radiometry is necessary for the absolute calibration of the cell.

An important advantage of the instrument described here is that it is self-contained, robust, and portable.

Measurements on Carbon Arcs.—Solid Carbons.

The outstanding result which emerges from measurements made on carbon arcs is that the great bulk of ultra-violet radiation given out comes from the flame of the arc and not from the poles. Thus, in working with 75 ampère arcs, which have a tendency to flare, whenever a flare occurred an observer at the instrument some 40 ft. away saw the gold leaf *jump* downwards, sometimes a big flare making it drop as much as half a scale division.

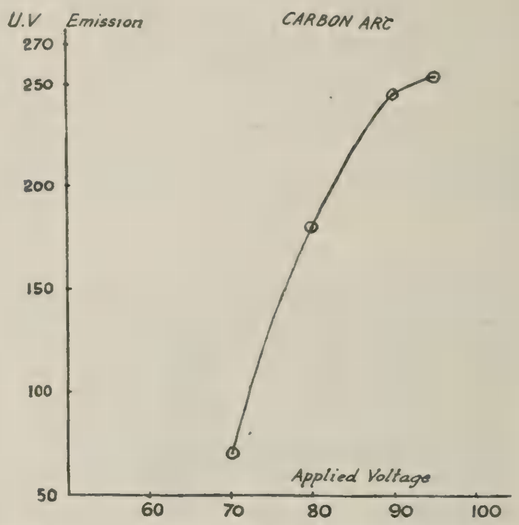
The emission with the carbon arc is, of course, not nearly so constant as that of the mercury arc. The crater tends to move round and round the carbons more or less rhythmically, with the result that the readings of the instrument go through corresponding cycles of maxima and minima. In the estimates of power given below regular readings during at least one complete cycle were obtained, so that the results given are considered to be fair average values of the effective power during an actual irradiation of patients. They were taken at the level of the arc at distances varying according to local conditions of some 20 to 40 ft. away.

The instrument is being adapted to make the averaging for fluctuations of intensity automatic by adding a condenser to it; the standard leak will then take 20 minutes or so to occur instead of 30 seconds, and the result obtained will represent the average power of the arc during the 20 minutes. It has to be noted that the fall of the leaf through the standard range means that a definite amount of ultra-violet energy has been delivered by the arc. It is anticipated that in this form the instrument will give a useful means of controlling dosage.

Variation of Ultra-violet Emission with Voltage.

The power of the 75 ampère arcs, having carbons of diameter 23 mm. and 30 mm., at the City Hospital, Aberdeen, has been measured, and its variations with varying input voltage have been determined. The results quoted below (see also Graph, Fig. 4) show that there is very great decrease of ultra-violet emission if the running voltage is allowed to drop some 10 or 15 volts.

Fig. 4.



Voltage.	Power.	Voltage.	Power.
70	70 units.	90	245 units.
80	180 ,,	95	253 ,,

This variation probably arises from the fact that a stable arc is shorter at low voltages than at high. There will thus be less flame, and what there is will be more shielded by the carbons if the applied voltage drops. Relative measurements of the emission of various types of carbon arcs have been made, and the emission has been found to depend largely on the construction and running conditions, a question which is being made the subject of further investigation. The results given below afford a rough guide to the power that may be expected, and refer in each case to arcs taking solid carbons. The effect of impregnation is to be studied later.

15 amp. type	Power, 12 units.
25 ,, ,,	,, 60 ,,
75 ,, ,,	,, 156 ,,

These results are in general agreement with those obtained by Lindemann [3] working with smaller arcs under carefully controlled laboratory conditions.

A set of typical readings are given below.

75 Ampère Carbon Arc.

Distance from arc to cell	420 in.
Diameter of diaphragm	15 mm.
Running voltage	77 volts.
Time of discharge (secs.)	Div. 11 to div. 7.

15·0	Effect of a flare	Average time, 24·5 secs.
38·0	Arc feeding itself	
21·8		
22·0		
21·2		
25·0		
22·6		
18·2	Effect of a flare	
27·4		
29·2		
28·8		

$$\text{Power of arc} = \frac{1}{100} \times \frac{D^2}{T} \times \left(\frac{22}{A}\right)^2 = \frac{1}{100} \times \frac{420^2}{24{\cdot}5} \times \left(\frac{22}{15}\right)^2$$
$$= 156 \text{ units.}$$

---

[3] Lindemann: Annalen der Physik, 1906, xix., 807.

The relative steadiness of the mercury arc is shown by the following readings :—

3 Ampère Mercury Arc, Type A.

Distance from arc to cell	89 in.
Diameter of diaphragm	8 mm.

Time of discharge (secs.) :—

26·2	26·2	Average time, 26·5 secs.
25·8	26·6	
26·2	26·6	
26·6	26·6	
26·8	26·2	
27·0	26·4	

Hence power of lamp, 22 units.

Measurements on Mercury Arcs.

Two types of mercury arcs have been investigated, an "atmospheric" type with tube length 5 cm., diameter 14 mm., taking 2·2 amps. at 100 volts across the tube ; it has a hemispherical white enamel bowl above it. This will be referred to as lamp A.

Lamp B is a vacuum type lamp, tube length 8 cm., diameter 15 mm., taking 2·8 amps. at 156 volts across the tube. It has a hemispherical polished metal bowl behind it.

Measurements have been made of the powers of both lamps. A typical series of measurements for lamp A has been given above. The small variations are assigned to slight alteration of arc length or supply voltage. They are even less in the case of lamp B.

Power of mercury lamp A	20·9 units.
,, ,, B	57 ,,

These measurements were made with the cell on a horizontal line from the lamp perpendicular to the tube length, the bowls being tilted to expose the quartz tubes completely. Thus the ultra-violet emission of B was about three times that of A.

Measurements have also been made of the distribution of ultra-violet energy round lamp A.

Along horizontal line perpendicular to tube length	20·9 units.
Along horizontal line at 45, perpendicular to tube length	14·7 ,,
Along line sloping downwards at 45, perpendicular to tube length	19·8 ,,
Vertically under lamp	32 ,,

Measurements are in progress of the effect of the bowl-shaped reflector in focusing the ultra-violet energy, and of the effect of voltage variation on the ultra-violet output.

General Considerations.

Another fact which requires consideration is that the instrument gives a directly valid comparison of the powers of sources of a similar nature—e.g., of two different sizes of carbon arcs, or of two types of mercury arcs. In comparing a carbon arc with a mercury arc, however, one other factor has to be taken into account, since the mercury arc is relatively richer in short waves than the carbon arc, in the region to which the instrument is sensitive. This is the usual difficulty of heterochromatic photometry, exactly analogous to the difficulty of comparing a lamp of bluish tint with a yellowish one ; to settle this point it is necessary to know how the sensitivity of the measuring instrument varies with the wave length. Preliminary tests have shown that the sensitivity of the instrument to different wave lengths in the band of the spectrum to which it responds (350 μμ to 200 μμ) is not far from uniformity. This detail is being investigated at present, but meanwhile it is not considered to be of great practical importance, at any rate until the problem has been solved as to what are the relative biological effects of the same amounts of ultra-violet energy applied in the form of mercury arc radiation, and of carbon arc radiation respectively.

It is interesting to note that a sheet of window glass held in front of the diaphragm stops all leak as completely as does the cardboard cap of the instrument, thus showing conclusively that only waves shorter than about 350 μμ actuate the instrument.

A further form of the apparatus is in use, in which the photo-electric leak across the cell is balanced by adjusting a resistance which allows current to flow in, so as just to neutralise the leak. The variable resistance, which must be of the order of 10 million megohms, takes the form of a thermionic valve with a very small quartz-insulated anode. In using this type, all that is required is simply to set the resistance till the gold leaf is stationary. Then the intensity of ultra-violet illumination is read off directly from the setting of the instrument, instead of indirectly from observation of the fall of the leaf, as in the first type described.

The work described above has been done by collaboration between the Natural Philosophy Department of the University of Aberdeen and the Health Department of the City of Aberdeen. The authors desire to express their indebtedness to Prof. Thomson for giving the use of the facilities of his research department, and for advice and criticism during the course of the work.

COLONIAL HEALTH REPORTS.

UNFEDERATED MALAY STATES.

Johore.—Mr. H. Marriott, General Adviser, in his report on this State for 1924 states that on an estimated population of 317,317 the birth-rate was 38·75 per mille and the death-rate 26·07 per mille. The infantile mortality for the year was 182·90 per mille, compared with 196·28 in 1923. The territory was again entirely free from cholera. There were 3 cases of plague and 2 of cerebro-spinal meningitis, all fatal ; 29 cases of chicken-pox and 205 of measles (including German measles) were reported ; there was 1 death from measles. Of small-pox there were 8 cases, all of which recovered ; and of influenzal pneumonia 6 cases, with 4 deaths ; 58 cases of enteric fever were recorded, with 16 deaths. There were 1798 cases of ankylostomiasis, with 68 deaths ; 677 cases of beri-beri, with 63 deaths ; 3 cases of blackwater fever (1 death), and 1810 of dysentery and diarrhœa (215 deaths). 12,514 cases of malarial fever were treated in Government and estate hospitals, and the percentage of deaths to total treated was 2·85, against 3·28 in 1923. 446 deaths were registered as being due to phthisis. The number of patients in the mental hospital at the end of the year was 176. Lepers in the Johore Leper Asylum numbered 70. All female lepers are transferred to the leper camp at Singapore. Admissions to the Government hospitals during the year were 15,987, and the number of attendances on out-patients at the various stations was 62,421. Johore Bahru showed the highest rainfall for Government stations, 126·72 inches, and the lowest was 76·74 at Batu Pahat. Temperature variations were not so great as during the previous year, there being a difference of 24 degrees between the highest maximum, 91 (Tangkuk), and lowest minimum, 67 (Kukub). Dr. R. D. Fitzgerald was confirmed as principal medical officer.

Kelantan.—The report for 1924 is signed by Mr. H. C. Eckhardt, Acting British Adviser. The total population at the 1921 census was 309,300, of whom 286,363 were Malays, mostly born in Kelantan. Of 12,000 Chinese, half were born in Kelantan, as were practically all of the 6000 odd Siamese. There were 34 admissions to the European hospital, and 2 deaths. In the native hospital at Kota Bharu there were 88 patients on Jan. 1st, 1924 ; 2059 patients were admitted during the year, and there were 35 deaths. The main ailments treated were malaria (274 cases), syphilis (163), yaws (346), ulcers (181), ankylostomiasis (123), beri-beri (4), and phthisis (69). In the cases of yaws very satisfactory results were obtained by the use of novarsenobenzol. The isolation camp at Kota Bharu was used for the isolation and treatment of phthisis and chronic bowel complaints ; there were 94 admissions and 36 deaths. There were 6 lepers in the leper camp at Kota Bharu at the beginning of 1924 ; 7 were admitted during the year, and 3 absconded. Treatment with sodium hydnocarpate and Heiser's Philippine formula, and the internal administration of cod-liver oil were actively carried out. As a result 2 cases were discharged with no outward signs of the disease and no microscopical findings of *Bacillus lepræ*. The new hospital at Kuala Krai was completed with accommodation for 50 patients. The number of out-patients treated at Kota Bharu was 24,153, at Kuala Krai 9384, at Tumpat 8928, at Pasir Futeh 6465, and at the Federated Malay States railways hospitals 9663. Travelling dispensers visited market-places and various kampongs at regular intervals, and treated 7057 children. A special hookworm campaign was carried out in Ulu Kelantan. It was well organised and most successful ; 7030 cases were treated with carbon tetrachloride. Twenty-three sporadic cases of choleraic diarrhœa, with 12 deaths, were reported from various villages. There was 1 fatal case of cholera. The health on estates was good. The routine medical inspection of estates was thoroughly carried out by Dr. W. J. Geale, medical officer at Ulu Kelantan. Dr. J. R. McVail was in charge of the medical department during the whole of the year, and Dr. Lim Shin Thwin assisted when necessary in Kota Bharu.

COLLOIDAL GOLD IN THE TREATMENT OF ALCOHOLISM.

To the Editor of THE LANCET.

SIR,—I note with interest in your issue of Nov. 28th that Dr. Bousfield confirms the value of colloidal gold in the treatment of alcoholism. I have used colloidal gold for six years (THE LANCET, 1922, i., 691, and 1924, ii., 491) and the longer I use it the more certain I am of its value. Dr. Bousfield uses atropine, a drug which I seldom found of use ; generally, in fact, the reverse, and I stopped using it several years ago. Why colloidal gold should be of such value in these cases one does not at the present know.

I am, Sir, yours faithfully,

STANFORD PARK,
Resident Medical Superintendent, Bay Mount,
Paignton, S. Devon.

Nov. 28th, 1925.

THE SHIPPING EXHIBITION AT OLYMPIA.

THE Shipping, Engineering and Machinery Exhibition held during the past fortnight at Olympia illustrated in a hundred ways the improvements being made on the material side of the business, but few devices to help the personnel were in evidence. One might look in vain for models of improved forecastles, or for examples of baths, lavatories, or water-closets, and there were surprisingly few ventilation exhibits. It appears that it pays a man to instal an expensive centrifugal extractor to recover oil from oily rags, but that to make it easier for the man who makes the rags oily to get the oil off himself is not a business proposition. In the long run, that is a mistaken view. One promising ventilating system is shown, the "Kelvite," with a quiet fan in each cabin regulated by a four-way switch: on, cold air; on, low heat; on, full heat; off. The indriven air is warmed as and if required, and the heating coils only function when the fan is running. It is claimed that air trunking is not needed, only a single shoot to the deck, and if that is found true in practice, ventilation of ships will become easier. The same firm (Kelvin, Bottomley, and Baird) exhibited an ingenious piece of apparatus, the size of a large thermos, for estimating the carbonic acid in furnace gases, giving the required figure (in percentage or parts per 10,000) in two minutes by a direct reading. The cost (£17) may put it out of reach of enthusiastic surgeons on ships. There was one beautiful instrument which, it is hoped, may abolish sea-sickness. This gyroscope, manufactured by the Sperry Company, has already performed feats almost as miraculous as that of keeping the ship on an even keel, and we wish it all success.

RADIANT HEAT IN OCULAR INFLAMMATION.

Dr. A. P. Schultz, of Brooklyn, sends us a reprint from *Solidarity* describing the relief afforded by intense dry radiant heat in his own case when he was suffering from iritis-keratitis. Before he tried this physical remedy he had obtained some mitigation of his pain from atophan in daily doses of 45 gr. combined with local treatment by dionin and thiosinamin; but from the moment of its application radiant heat relieved pain and later, he is sure, helped to clear up corneal infiltration. There is, we might add, nothing very new in this use of dry radiant heat; the late Mr. R. W. Doyne wrote a paper describing the treatment in the Transactions of the Ophthalmological Society for 1900. But Dr. Schultz's testimony is striking confirmation.

THE GREAT PLAGUE IN LONDON.

IN the *Journal of the London Society* for November is an account of the Great Plague of London in 1665, by Mr. W. G. Bell, F.S.A. The map accompanying the paper shows how the mortality varied from district to district, but was less in the walled city, concentrating on the poorer inhabitants of the jerry-built slums outside the walls, Aldgate, Bishopsgate, and Moorgate. Mortality was also high about Westminster Abbey. The outbreak began in the ward of St. Giles-in-the-Fields (about the spot where New Oxford-street and Charing Cross-road now join). It was intense in the west in July, gradually spread east, and reached its peak there in September. Burial was a difficulty, some churchyards became so overcrowded as to raise their level two or three feet above that of the neighbouring streets—as may still be seen—and plague pits were opened, the nearest in Aldgate. Infection was supposed to spread through the air or from the soil, hence people stuffed the keyholes of their doors to exclude the outer air, and they killed cats and dogs which might have helped to keep infection at a distance. The Great Fire in the next year burned out the walled city, but did good to the slums outside, by making way for better buildings and better sanitation in the areas which it cleared.

DRUG SMUGGLING.

IMPORTANT seizures of illicit drugs in the Straits Settlements, totalling nearly 300 lb. of morphine hydrochloride, have been reported to the League of Nations by the British Government. The drugs were shipped from Antwerp to the Far East, but were intercepted at Singapore. The following is a typical story:—

> On the arrival of the ss. *Haruna Maru* from Europe on May 25th, a party of revenue officers went on board and examined a consignment of seven casks which were declared to contain carbolic acid. Six of the casks were standing on end with the marks downwards, but the seventh, which was right end up, was opened first and found to contain 63 lb. of morphine hydrochloride. The other six casks contained carbolic acid as declared. The casks were similar to beer casks and held about 50 gallons each. On examination it was found that inside each cask was a smaller rough wooden cask containing a large tin packed in sawdust. In the case of the six genuine casks, these tins, which were cylindrical, had circular soldered lids at the side of the upper plane surface, as in kerosene oil tins, and were filled with solidified carbolic acid. In the case of the seventh cask, the tin was larger and the "lid" was not soldered down but could be prized open. When this lid was removed it appeared that this tin also was filled with carbolic acid. Further examination, however, showed that the acid was confined in a small compartment about 7 in. in diameter, soldered to the upper surface round the "lid." The outer tin was then cut open and found to contain a smaller tin packed around with sawdust and about 150 lb. of sheet lead, evidently put in to make up weight, and its contents were 63 lb. of pure morphine hydrochloride. The master of the ship was fined $1000 and the seven casks confiscated.

The Secretary-General of the League has sent to the Powers having extra-territorial rights in China a copy of a resolution adopted by the League's Advisory Committee in August last and approved by the Council, to the effect that those Powers "should, if they have not already done so, make regulations, the breach of which shall be punishable by adequate penalties, to control the carrying on by their nationals in China of any trade in the drugs to which Chapter III. of the Opium Convention applies."

DIRECT INJECTION OF ADRENALIN INTO THE HEART FOR ARREST DURING ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—In the following case the heart and respirations ceased and revived again after the injection of adrenalin into the heart. The case shows some variation from the two reported in THE LANCET (1924, ii., 746).

The patient was a healthy young woman suffering from sterility, and I was about to dilate the cervix and curette her. The assistant had some difficulty in giving the chloroform, and must have dropped too much on the mask, for while I was waiting to begin I discovered that the patient had stopped breathing. Her pulse could not be felt, and no heart sounds were heard. I immediately started artificial respiration, and gave hypodermics of strychnine, pituitrin, and camphor in oil. There was no reaction, and the cornea looked glazed. I then injected adrenalin through the fourth space into the heart, and heart and lungs responded at once; there must have been at least five minutes interval since they had ceased acting. After waiting a few minutes, during which the patient vomited slightly, I quickly did the operation, and before it was over she began to show some signs of feeling pain. Within half an hour she was round, and able to speak, and she had no trouble of any kind afterwards. When I saw her several hours later in the evening she was very bright and had already taken food.

In the cases previously reported the patients did not recover consciousness for a long time, but my patient came round just in the same manner as any ordinary operation case does.—I am, Sir, yours faithfully,

Quetta. E. G. STUART, M.B. Lond.

PATHOLOGICAL AND BACTERIOLOGICAL LABORATORY ASSISTANTS' ASSOCIATION.

THIS Association was founded in 1912 with the object of improving the status of the laboratory assistant by raising the standard of technical knowledge through the medium of an educational programme culminating in examinations for certificates of proficiency in laboratory technique.

The Association consists of: (*a*) life members; (*b*) honorary members, limited to 20; (*c*) registered members who possess one of the Association's certificates of proficiency; (*d*) ordinary members 21 years of age and over with three years' training in a recognised pathological or bacteriological laboratory; and (*e*) junior members under 21 years or with less than three years' experience. There are at present 102 registered, 158 ordinary, and 97 junior members, who are organised in branches throughout Great Britain. The governing Council of the Association consists of the president, who must be a member of the Pathological Society of Great Britain and Ireland, the vice-president, certain officers and divisional representatives elected by the members.

The ordinary meetings of members are arranged by the branches and are largely educational in character. To encourage the systematic teaching of the junior members, lectures and classes in the technique of pathology and bacteriology are conducted by members of laboratory staffs and by senior members of the Association. General meetings are held from time to time; a congress lasting five days for the discussion of papers and exhibition of methods and specimens was held in Edinburgh in 1924, and another will be held in Cambridge in 1927. An official organ—*The Laboratory Journal*—is issued to members quarterly; in addition to Association news it contains original articles and abstracts of technical interest to laboratory workers. There is an employment bureau and notices of vacancies are sent to members who register. The examinations are held annually in July in London and other convenient centres. The Secretary of the Association is Mr. H. P. Hudson, Panama Villa, Trumpington, Cambs.. and the Overseas Corresponding Secretary is Mr. W. J. Muggleton, 82, Chapter-road, London, N.W. 2.

Schorstein Memorial Lecture

ON

LYMPHADENOMA

(HODGKIN'S LYMPHOGRANULOMA).

Delivered at the London Hospital on Dec. 4th, 1925,

BY SIR HUMPHRY ROLLESTON, BART.,
K.C.B., M.D. CAMB.,

REGIUS PROFESSOR OF PHYSIC IN THE UNIVERSITY OF CAMBRIDGE; PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE honour of giving the Schorstein lecture is a welcome opportunity of paying a brief tribute to a contemporary of peculiar charm and broad culture whom I first met at a small class in the late 'eighties, held by the late E. E. Klein, on the then recently recognised subject of bacteriology.

HISTORY AND NOMENCLATURE.

Morgagni (1769) briefly noted the condition, and no doubt there are other early records of the morbid change, but Thomas Hodgkin (1798–1866), demonstrator of morbid anatomy at Guy's Hospital (1825–37), is usually regarded as its sponsor. In 1832 he described "Some Morbid Appearances of the absorbent Glands and Spleen," recording six cases of his own and one of Sir Robert Carswell's. How many of these can be accepted as definitely examples of the disease now called after him it is rather difficult to decide; Samuel Wilks excluded two of the six original cases, but later critics have been more drastic; for example, Dorothy Reed and Symmers accepted two only of the seven. Except for a reference in Bright's lectures on Abdominal Tumours, Hodgkin's paper did not attract any attention, and probably would have remained unnoticed but for the loyal action of his junior, Samuel Wilks, who, in the course of a paper "On Cases of Lardaceous Disease and Some Allied Conditions," in 1856 included an account of a "Peculiar Enlargement of the Lymphatic Glands," which, though not lardaceous, was described because it is either a variety of it or closely akin to it. This is interesting as amyloid disease occasionally complicates Hodgkin's lymphogranuloma, though not so commonly as does tuberculosis which several writers have regarded as its underlying cause. After this paper was completed, but before it was finally printed, Wilks found that Hodgkin had described some of the cases actually in his series, and being one of the editors of *Guy's Hospital Reports* added a paragraph to say that had he been aware of this some of the statements pointing to the originality of his observations would not have appeared. In 1865 he collected 15 cases and perpetuated Hodgkin's name by calling them after him; this was just before Hodgkin's death from dysentery at Jaffa in 1866 and long after he had ceased to be connected with the hospital.

In the meanwhile, Virchow (1864) had described the disease from a pathological point of view as lymphosarcoma, an unfortunate name, as it is often used for a special form of an undoubtedly malignant growth. Cohnheim, in 1865, used the term pseudo-leukæmia for cases in which the glands showed the histological picture of leukæmia without the corresponding blood change, or as it would now be called aleukæmic leukæmia or aleukæmic lymphadenosis. The names lymphosarcoma and pseudo-leukæmia have caused much confusion, but at this long interval of time it is not difficult to be wise. In the same year (1865) Trousseau gave one of his famous clinical lectures on *adénie*, a name which in the following year was expanded into lymphadenoma by Wunderlich, the title of whose paper is worth quoting in full as an epitome of the foregoing sentences—"Pseudoleukämia, Hodgkin's Krankeit oder multiple Lymphadenome ohne Leukämia." Cornil and Ranvier (1869) adopted lymphadenoma, and apparently it thus came to the notice of Murchison, who introduced it at the Pathological Society in 1870. But recently Agasse-la-font has drawn a distinction between Trousseau's adénie and Hodgkin's disease or lymphogranulomatosis.

From its familiarity and recognised meaning in this country the term lymphadenoma is the most convenient, but etymologically it is a little ambiguous, as it is not clear whether it implies a tumour of lymphadenoid tissue (lymphaden-oma) or, on the analogy of other adenomas, an innocent growth (lymph-adenoma), and also because it quite definitely suggests that it is a neoplasm, just as the alternative names, recently in vogue, lymphogranulomatosis, lymphomatosis granulomatosa, and granulomatosis, which some prefer, as the lesion is not necessarily confined to lymphadenoid tissues, declare it to be an infectious granuloma. From an international point of view, however, "lymphadenoma" has the drawback of being used by some writers, especially the French and by Ewing (1923), and Fox and Farley in America, for conditions, such as lymphoma and hyperplastic lymphadenitis, different from Hodgkin's disease; lymphogranulomatosis benigna has been applied to Boeck's sarcoid of the skin and allied conditions (Schaumann), and malignant lymphadenoma and lymphogranulomatosis maligna or perniciosa has been used as a synonym for Hodgkin's disease.

The eponymous title, Hodgkin's disease, has the advantage of avoiding any hypothesis as to its nature, but it might be thought that as Sir Samuel Wilks was really instrumental in its recognition, it should in justice be called Hodgkin-Wilks disease. The name Hodgkin's lymphogranuloma, used for 17 years by Prof. H. M. Turnbull and also employed by Ewing, has much to recommend it as leaving no doubt as to what is meant. In what follows the names lymphadenoma, Hodgkin's disease, and Hodgkin's lymphogranuloma will be used as synonymous.

The *history of the histology of lymphadenoma* is of some interest. The credit of first describing the lymphadenoma cells and the other features in the glands has been variously ascribed in different countries to native workers on account of want of familiarity with the work of foreign observers. In 1864, the year before Sir Samuel Wilks made Hodgkin's name immortal by attaching his name to the disease, Virchow described the large multinuclear or "lymphadenoma cells" which subsequent observers, among them Langerhans (1872) and C. Sternberg (1898), also noted, so that the cells are sometimes called after these later pathologists.

In 1878, in the course of a debate on lymphadenoma and allied conditions, W. S. Greenfield described "a large number of multinuclear cells containing from 4 to 8 or 12 nuclei," with a drawing which, though quite forgotten, was recognised in 1902 by Butlin as quite characteristic; though he never published any further account, Greenfield had fully worked out the histological appearances and had been accustomed to give them in detail to his Edinburgh students (S. MacDonald). In 1892 Goldmann pointed out the local eosinophilia in lymphadenomatous glands. But the characteristic microscopic appearances of lymphadenoma were not generally recognised until F. W. Andrewes gave a full account of the histological appearances independently of and practically synchronously with Dorothy Reed's similar description.

NATURE OF HODGKIN'S LYMPHOGRANULOMA.

Four views as to the nature of Hodgkin's lymphogranuloma may be mentioned—namely, that it is (1) an atypical form of tuberculosis, (2) a specific infective granuloma of unknown nature, (3) a new growth, and (4) a transition between a granuloma and a new growth.

(1) *The relationship of lymphadenoma and tuberculosis* has long been discussed. Some of Hodgkin's original cases were almost certainly tuberculous, and even now to the naked eye the large-celled tuberculous hyperplasia of the lymphatic glands is often indistinguishable from lymphadenoma. In 1898 Carl Sternberg, of Vienna, considered that lymphadenoma was a special form of tuberculosis, just as lupus is of cutaneous tuberculosis, and hyperplastic tuberculosis of the cæcum and appendix a peculiar form of intestinal tuberculosis; he obtained evidence of tuberculosis in 10 out of 15 cases; but this was opposed on the ground, dimly foreshadowed by W. H. Dickinson in 1878, that the tuberculous invasion was a secondary process which the existing lymphadenomatous lesion favoured. Inoculation experiments were found to give varying results, sometimes positive, sometimes negative (Andrewes; Reed; Longcope), and it appears that the positive results were due to a mixed infection, and the negative to uncomplicated lymphogranuloma. This interpretation seems convincing, but it has not been accepted universally; Ewing, with the weight of special experience, considers the evidence in favour of tuberculosis somewhat formidable.

In 1910 Fraenkel and Much, using the antiformin method, described a granular form of the tubercle bacillus which they found in 11 out of 12 lymphadenomatous glands free from the structural changes characteristic of tuberculous adenitis, and considered that in addition to this organism some special constitutional anomaly was necessary to account for the lesions. Dr. Negri and Micremet, in 1913, described a similar organism, and in 1923 Fraenkel and Much, employing a special technique, found their form of the tubercle bacillus in nearly all the cases they examined. Almost simultaneously Kuczynski and Hauck described a mycelial form in the multinuclear cells, an observation which appeared to fit in with the tuberculous origin, but this has not been confirmed by Sternberg. In 1924 Grumbach obtained a bacillus resembling Fraenkel and Much's by blood culture from a patient with the relapsing fever of Pel-Ebstein. Lukes and Jelinck, however, found Much's granules in three out of 11 persons without either tuberculosis or Hodgkin's lymphogranuloma.

It has been urged in favour of the tuberculous nature of Hodgkin's disease that the cases may terminate in generalised tuberculosis; this had not been common in my experience, but its occurrence might be explained by the view that the presence of Hodgkin's lymphogranuloma favours tuberculous infection or activates it when latent.

(2) *A Specific Infection.*—Various organisms have been described as responsible for Hodgkin's lymphogranuloma, but none of them can be regarded as proved. The most attractive is a protozoal (Löwit) or spirochætal (White and Proescher) origin on account of the eosinophilia in the glands, the occasional hæmic eosinophilia, and the well-marked reaction, in the early stages at least, to arsenic. Dreschfeld, in 1892, and Delbet, in 1895, described a bacillus, as did Ford Robertson and Young, in a case reported by Byrom Bramwell. But the most persistent effort in this direction is that of Bunting and Yates, who found a Gram-positive pleomorphic diphtheroid bacillus which Bunting states can be found in every case and by experimental inoculation made to produce the early histological changes seen in man; but the last two statements have not been confirmed.

(3) The view that Hodgkin's lymphogranuloma is a new growth, allied to sarcoma or endothelioma, is probably derived from the impression that this follows from its extension beyond the limits of lymphoid tissues and its infiltration of tissues, such as muscle and bone, which do not contain any lymphadenoid tissue; but in this extension there is nothing incompatible with the behaviour of the infective granulomas, tuberculosis, syphilis, and actinomycosis. On the other hand, Gye and Barnard's discovery of an ultramicroscopic virus and a specific factor for new growths, and the existence of infective sarcomas make discussion of the pros and cons of the neoplastic nature of Hodgkin's lymphogranuloma rather an academic exercise than one of practical utility.

(4) The compromise that Hodgkin's disease is a transition between an inflammatory formation and a neoplasm and shares characters with both of these processes has been supported by Symmers,[84] who classes it with mycosis fungoides, Cohnheim's pseudoleukæmia, Sternberg's leukosarcoma, and Gaucher's disease. This view is expressed in Dietrich's title granuloma-like sarcoma of lymphatic glands, and by "granulation tissue tumour."

It has been stated by Symmers [83] that Hodgkin's lymphogranuloma is a systemic disease which simultaneously attacks the lymphadenoid tissues widely in the body. In the light of ordinary clinical experience this pathological conception can only pass muster if it be assumed that the simultaneous involvement remains latent in many parts while it advances in one focus.

As the cause of Hodgkin's lymphogranuloma has not been established it is premature to divide it into different forms on the analogy of enteric fever which includes infections with *B. typhosus*, *paratyphoid* A, and *paratyphoid* B. But it is tempting to imagine that there are several allied forms of a disease characterised by much the same histological appearances but differing in their virulence, in their tendency to sarcomatous transformation, and so in their clinical manifestations. Symmers [84] definitely describes two forms of the disease, one confined to the lymphadenoid tissues, the other mechanically infiltrating other structures, skeletal muscles, blood-vessels, and so forth. The differences in the histological pictures as regards the presence of eosinophile cells and the puzzling variations in the blood picture are at least compatible with this view. But, on the other hand, the factor of the resistance of the individual's body must, of course, be taken into account in explaining the differences in the course and manifestations of this as of other diseases.

NATURE OF MALIGNANCY IN HODGKIN'S LYMPHOGRANULOMA.

That Hodgkin's lymphogranuloma is malignant in the sense that it leads to death is undoubted, and it differs from tuberculosis, which in many respects it closely resembles, in being constantly fatal and not becoming obsolete.

It generalises like tuberculosis, and may appear in situations such as the liver and kidney, where the amount of lymphoid tissue is small, and in muscle (vide Figs. 1 and 2) in which there is none. But mere generalisation is in keeping with the characters of an infective granuloma. Even if it be held that true Hodgkin's disease is confined to lymphadenoid tissue, the occurrence of lymphogranulomatous masses in the liver and kidneys might be explained on the hypothesis that there is a compensatory hyperplasia of the lymphoid tissue around the vessels, and that subsequently this becomes infected with the virus of the granuloma (Longcope). But further evidence suggesting malignant characters, such as invasion of adjacent bone and the histological characters of sarcoma, described years ago by Yamasaki and by Karsner, are now established, and Ewing considers this transformation into sarcoma ("Hodgkin's sarcoma") as a tumour *sui generis* and as by no means rare. He describes the new cells as endothelial in origin, but losing this character and appearing as large round cells, so that the term endothelioma is hardly applicable. Such a transformation as the result of long-continued irritation is, of course, well recognised, and Ewing[20] has described it in lymphatic glands affected with chronic granulomatous infection. The occurrence of Hodgkin's sarcoma as a late result of Hodgkin's lymphogranuloma is rather remarkable, as it is very seldom recognised in the other infective granulomas.

The development of sarcoma in Hodgkin's lymphogranuloma might be explained in one of two ways: (1) that some of the constituent cells of the lymphogranuloma proliferate so vigorously as to become a sarcoma, or (2) that the tissues surrounding a mass of lymphogranuloma are excited by the chronic irritation to a proliferation which eventually becomes sarcoma; this process Ewing compared with the occurrence of cutaneous squamous-celled carcinoma in the site of lupus.

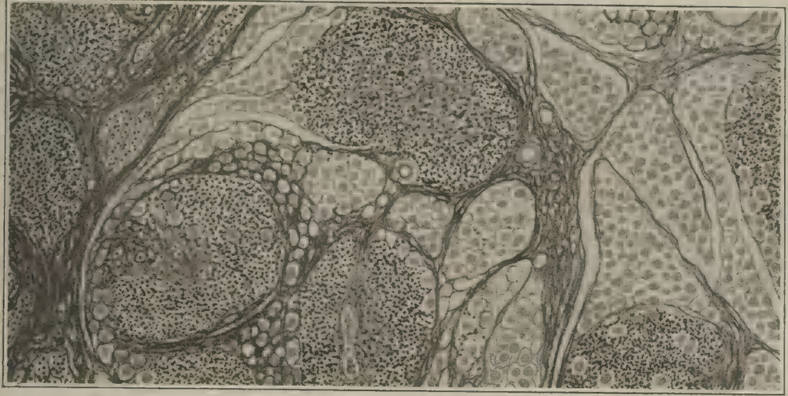
Prof. H. M. Turnbull, while fully recognising the existence of the condition which Ewing [21] terms Hodgkin's sarcoma, regards it as the "lymphosarcomatoid" form of Hodgkin's lymphogranuloma and as inflammatory rather than neoplastic. Lymphosarcoma—the form of growth concerned in the malignant transformation of Hodgkin's disease—he considers as closely allied to it, and like it an inflammatory and not a neoplasm.

The Blood.

As the bone marrow, lymphatic glands, spleen, liver, and the reticulo-endothelial system regulate the formation and destruction of the blood-cells, it is obvious that, as these organs are the chief sites of Hodgkin's lymphogranuloma, the blood counts should be correspondingly affected.

If the lesion was one of the reticulo-endothelial system in particular and at times affected these phagocytic cells to the exclusion of the others, it might be expected that in the early stages of proliferation there would be increased hæmolysis, later followed, as the result of destruction and fibrosis, by a diminished hæmolysis with a rise in the red blood count and even a polycythæmia; but, unless the early increase in the platelets described by Bunting be regarded in the light of a hæmolytic process, and not as evidence of marrow stimulation, nothing of this kind occurs, even in the few instances of the splenic form of Hodgkin's lymphogranuloma. On the other hand, this last argument is not supported by the blood picture in fibrotic conditions of the spleen, such as chronic splenic anæmia in which polycythæmia is not seen; and there are only most exceptional instances of massive tuberculosis of the spleen in which it has been recorded (vide Weber [91]). Sooner or later there is a secondary anæmia which eventually may become so grave as to demand transfusion. How far in individual cases this is due to one or more of several causes it is difficult to say; toxæmia, infiltration of the erythroblastic bone-marrow, exhaustion after compensatory or arsenical stimulation of the bone-marrow, or the long-continued treatment by X ray exposures may each play a part.

FIG. 1.



Iliacus muscle showing infiltration by Hodgkin's lymphogranuloma; small cellular and fibro-cellular nodules to the right of a larger more fibrotic nodule. Obj. 1 in., oc. Zeiss 4. (By the courtesy of Prof. H. M. Turnbull.)

The white count does not show any constant or characteristic change. Usually leucocytosis is absent and there may be a leucopenia with a relative lymphocyte increase, especially, I believe, when the spleen is predominantly affected, a view shared by Weber.[95] Bunting described the blood picture in two stages: in cases under a year's duration, no leucocytosis, a relative lymphocytosis, diminished eosinophiles, and increase in the transitional cells. In more advanced cases when the disease is spreading widely there is a leucocytosis with a raised polymorphonuclear count (75–90), and later from exhaustion of the bone-marrow absence of blood platelets. Stewart lays most diagnostic reliance on a relative increase of large mononuclear cells—not lymphocytes—especially of the transitional type (19–33 per cent.); and also attaches importance to an absolute and relative neutrophile leucocytosis and to a relative and absolute eosinophilia. The rather exceptional occurrence of eosinophilia, which is specially seen in the rare acute cases, is interesting in connexion with the characteristic though not absolutely constant presence of eosinophile cells in the glands. These cells are probably not produced locally, but are embolic immigrations from the bone-marrow (Goldmann; D. Reed; Symmers[84]; Turnbull). In a case of acute lymphadenoma Lincoln found 68 per cent. of eosinophiles and in his collection of previously recorded cases found that the highest count was 24·5 per cent. A percentage of 88 eosinophiles in a differential count of 83,000 leucocytes was recorded by Desjardins and Ford. Among 20 cases of the disease Pepper found it in 4 or 5 per cent. The relation of eosinophilia to pruritus has attracted much attention; the almost constant relation has been insisted on by Favre and Mariani, and the former drew an analogy between adénie éosinophilique prurigène and hydatid pruritus. No doubt eosinophilia and pruritus may be associated in lymphadenoma, but they may also occur independently. In a case without pruritus seen in 1910 there was 26 per cent. of eosinophiles, and in an advanced case under Dr. E. Bellingham Smith in St. George's Hospital the count was 69 per cent., but pruritus was then absent, though present at an earlier stage when the eosinophile percentage was 39. Megacaryocytes on their way from the bone-marrow to form the "lymphadenoma cells" in the lymphatic glands have been found in the blood-stream (Symmers[84]).

It would be interesting to correlate the blood picture with the contemporary changes in the structure of the lymphatic glands. But the complicated cellular changes in the lymphogranulomatous tissue and the variations in the blood picture make this a difficult problem. A lymphocytosis would correspond with a proliferation of the lymphoid cells; but that the leucopenia in the early stage would be more easily correlated with inhibition of the bone-marrow than with its destruction is rendered probable by the occurrence of a polymorphonuclear leucocytosis in the later generalisation of the disease.

The question whether lymphadenoma is primarily a proliferation of the lymphoid cells or of the reticulum has a bearing on the condition of the blood. If with Symmers[84] the primary change is regarded as a proliferation of the lymphoid cells, their escape into the blood and a lymphocytosis would be expected. Whereas if the first and essential change is proliferation of the endothelial cells and framework of lymphadenoid structures (Turnbull; Ewing; Webster), and proliferation of the lymphoid cells, when it occurs, a secondary process compensatory for destruction of lymphoid cells elsewhere (Longcope), the absence of any characteristic blood picture is more satisfactorily explained. Acceptance of the view that the process s primarily a proliferation of the endothelial and reticular cells (the distinction between them being difficult) has been followed by the suggestion that it is, like Gaucher's disease and xanthoma (Krumbhaar), a disease of the reticulo-endothelial system—a reticulo-endotheliosis (Piney); but if it were, the Kupffer's cells in the spleen and liver should be constantly and predominantly affected, and this is not the case.

In the past, when blood counts were less minute, leukæmia was stated sometimes to supervene on Hodgkin's disease. This sequence is not supported by modern evidence, but the discovery of leukæmic blood changes would probably rule out a previous diagnosis of Hodgkin's disease. There may well be an analogy between the two questions of (1) the occurrence of Hodgkin's sarcoma or lymphosarcoma (in Turnbull's interpretation), and (2) leukæmic or proliferative changes in the blood picture. That stimulation of the bone-marrow may occur in cases of widespread generalisation of Hodgkin's disease is shown by the occurrence of a polymorphonuclear

FIG. 2.

leucocytosis, and it is at least conceivable that riotous proliferation of the bone-marrow, analogous to sarcoma and leukæmia, might follow.

The Relapsing Fever of Lymphadenoma.

The *relapsing fever*, first recorded in 1870 by Murchison, but often called Pel-Ebstein after the descriptions by these two writers in 1885 and 1887, has attracted much attention, as shown by the papers of H. B. Shaw, F. Taylor, McNalty, Weber,[90] A. J. Hall and Douglas, and Galloway. Hall and Douglas estimate that less than 50 cases have been recorded; but it is probable that it is comparatively seldom reported rather than that it is as rare as is often stated, and Hall and Douglas appear to share this view, for they write, "in looking over old records of these cases it is surprising to find how many of them show a definite tendency to recurrent pyrexia." I am much indebted to Dr. A. S. MacNalty, who has given me the opportunity of seeing his notes of 11 cases additional to the 32 on which his paper in 1911 was based; among his new cases is one in a boy aged 3 years, the youngest on record. In a recent thesis for the M.B. degree at Cambridge, Mr. H. F. Brewer collected from St. Bartholomew's Hospital in four years, 1921–5, 62 (42 confirmed microscopically) cases of Hodgkin's lymphogranuloma, among which there were nine cases of relapsing fever.

This periodic fever is comparable with a protozoan infection such as malaria, relapsing fever, and rat-bite fever, but has a longer span of 15 to 25 or even 36 days (Hall and Douglas). Although bacteria have sometimes been obtained by blood cultures, negative results are the rule, and there is not any convincing evidence of a secondary infection, probable as it would seem. But some change must occur, otherwise every case of Hodgkin's lymphogranuloma would show the relapsing type of fever. Symmers's view that the fever is due to absorption from areas of focal necrosis, especially in the spleen, which he finds are always present in enormous numbers in the chronic relapsing fever, has much to recommend it, and had been present to my mind before I read his paper in which he compares the sequence of events with the fever in cases of necrotic hypernephromas.

Dr. MacNalty has generously put at my disposal an analysis of 40 collected cases of this relapsing fever; 30 were males and 10 females, and half the cases occurred between the ages of 10 and 30 years, the oldest being a woman of 54 and the youngest a boy aged 3 years. He divides the cases into three clinical groups, the first, far the commonest, in which the external glands are moderately enlarged and may become soft, tender, painful, and, but not constantly, enlarge during the pyrexial periods. In the second, a rare form, the glands, small in the apyrexial intervals, with the onset of fever rapidly swell up, becoming extremely large, tender, hot, and painful, the skin over them becoming red or purple and sometimes œdematous. With the end of the febrile attack the glands and spleen shrink to an extreme degree. In the third form, of which he collected eight cases, the only glands affected are the internal, though the spleen may be palpable. As regards the duration of the relapsing type the extremes were five weeks and five years, the disease being more rapid when the enlargement was confined to the deep glands. When the internal glands alone are affected the differential diagnosis, of course, covers a large field, such as enteric fever, malignant endocarditis, and other conditions which need not be discussed. But reference should be made to the simulation of the Pel-Ebstein fever by tuberculosis. Among 500 cases of pulmonary tuberculosis at the Brompton Hospital MacNalty found six with a recurrent fever; in such cases splenic enlargement may be a clue. He also insists on the close clinical resemblance to Hodgkin's disease of widespread tuberculous adenitis.

The *primary site of Hodgkin's lymphogranuloma* is a subject of some practical importance, for enlargement of the superficial lymphatic glands being usually the first indication of lymphadenoma, has accordingly been generally regarded as the starting-point of the disease. But it does not follow that the glands first palpably enlarged are necessarily those first attacked. Symmers,[84] from pathological experience, contends that this conception is erroneous, and that primary enlargement of the abdominal or of the abdominal and thoracic glands combined is ten times commoner than primary enlargement of the cervical glands. With this Ewing [21] agrees, and adds that the enlarged superficial glands which first attract attention are merely the outlying portions of an internal lesion. The idea that the glandular enlargement on the neck may in any given case be secondary rather than primary, and, indeed, be analogous to the glandular metastases in malignant disease inside the chest and abdomen, should be more constantly in our minds, and, being based on post-mortem observations, demands clinical confirmation by systematic X ray examination of the chest in every early case; for if intrathoracic or abdominal involvement is present this should obviously be treated by deep radiation. The unsuspected existence of intrathoracic lymphogranuloma may help to explain some apparently hyperacute cases, such as Brunner's patient, a woman aged 27 years, who died with two weeks' symptoms suggesting acute cardiac failure, the necropsy revealing extensive Hodgkin's disease.

Enlargement of the superficial lymphatic glands may disappear under treatment, either entirely or partially, while insidious implication of the deep abdominal and thoracic glands progresses, and the patient becomes anæmic, emaciated, and eventually dies. Intercurrent infections, such as erysipelas, appendicitis, and lobar or influenzal pneumonia, may be followed by diminution in size or disappearance altogether of the glands which, however, subsequently reappear. The same temporary improvement, especially in the blood count, may occur in leukæmia, an event which is of interest in connexion with Symmers's [84] contention that Hodgkin's lymphogranuloma and myeloid leukæmia "are probably different quantitative responses to the same type of provocative agent." Further, this reaction is of interest in connexion with W. B. Coley's treatment of Hodgkin's lymphogranuloma by the mixed toxins of erysipelas and *Bacillus prodigiosus* and radium.

The variations in its distribution are on much the same plane as those in the infective granulomata, such as tuberculosis and syphilis, and it may be suggested that its localisation is determined by two factors: (1) the variations in the resistance of the different parts of the body, (2) the accident of a large dose of the virus at any one site. When generalisation occurs, the spleen is more often invaded than the liver, according to Longcope and McAlpine in the percentages of 57 and 48.

Intrathoracic Form.

The intrathoracic form is probably more frequent and primarily responsible for palpable glandular enlargement in the neck than is generally recognised. For a considerable time pressure symptoms may be absent, although a skiagram shows well-marked invasion of the mediastinum. The thymus may be predominantly affected and from this focus the disease may spread over the pericardium and even to the myocardium; fatal effusion into the pericardium may follow, and I have seen a chylous effusion. In 1924 Symmers collected five cases of predominant thymus localisation; but probably it is much more frequent than these figures would suggest, and the question arises what proportion of mediastinal sarcomas should be regarded as Hodgkin's sarcoma, for there seems to be a special tendency to sarcomatous change in these mediastinal lymphogranulomas (Ewing [21]). The bronchial glands are often enlarged and from them the disease may creep along the bronchi into the lungs. The first clinical manifestation may be acute pleurisy, and palpable enlargement of glands may follow later. Pleural effusion, which requires repeated tappings, is a feature of some cases. In one case the effusion caused sudden death, and in another it was chylous. In the presence of a comparatively small effusion the dyspnœa may be out of proportion to the amount of fluid; in some cases this is obviously due to pressure exerted by enlarged glands on the bronchi, as shown by stridor and skiagraphy. Symmers [84] has recorded two cases with remarkable thickening of the pleura with Hodgkin's lymphogranuloma. Pressure symptoms resulting from compression of the trachea, bronchi, veins, and nerves make this the most distressing form of lymphadenoma, as the patient may eventually become strangled, deeply cyanotic, and terribly distressed. Before this stridor may be noticeable on exertion only; I have seen attacks of dyspnœa terminating in the expulsion of fibrinous cases. The fever of the Pel-Ebstein type may suggest pneumonia, and Weber considers that patients taking arsenic are prone to pneumonia, which, however, usually runs a favourable course

In Dr. C. H. Miller's case, from which the sections showing Hodgkin's disease in muscle were taken, there was a large mediastinal growth, involving the root of the right lung and causing racemous lymphogranulomatous bronchitis, peribronchitis, and peribronchial pneumonia, with catarrhal, fibrinous, and fibroblastic pneumonia in the intervening pulmonary tissue of the upper and middle lobes of the right lung (H. M. Turnbull). Paracentesis of the right pleura, giving exit to three pints of clear yellow fluid (97 per cent. lymphocytes) was followed by pneumothorax. Death was due to the intrathoracic condition.

Pressure on the superior vena cava and innominate veins may induce cyanosis, distension of veins, œdema of the face and conjunctivæ, and an œdematous boggy condition in the supraclavicular fossæ. Clubbing of the fingers (Turnbull) and chronic pulmonary osteo-arthropathy (Weber and Ledingham) have been reported. Dysphagia may occur, but is seldom prominent. Pressure on the recurrent laryngeal nerves may lead to abductor paralysis. The oculo-cardiac reflex may be exaggerated (Jacob).

ABDOMINAL MANIFESTATIONS.

The abdominal manifestations of Hodgkin's lymphogranuloma may be divided into (1) the peritoneal, (2) retroperitoneal, (3) gastro-intestinal, (4) splenic, (5) hepatic, and (6) renal forms. The last three are extremely rare in a predominant form.

(1) The *peritoneal form*, due to affection of the mesenteric glands, may imitate tuberculous peritonitis and give rise to ascites, which is usually serous, but in rare instances has been chylous or pseudo-chylous; among 46 cases Schreiner and Mattick had two with chylous ascites, and Schölberg and Wallis in their collections of 102 cases of chylous and 71 cases of pseudo-chylous found two in each group due to Hodgkin's disease. Ascites, which may be the first physical evidence of the disease, is occasionally associated with jaundice due to pressure on the bile-ducts by enlarged glands in the portal fissure. This jaundice may intermit; I have twice seen the jaundice appear and disappear with the periodic onset and resolution of the Pel-Ebstein fever. Enlargement of the glands in the neighbourhood of the liver and fever may imitate cholecystitis or hepatic abscess, as in a case I saw after laparotomy had revealed the true state of affairs.

(2) In the *retroperitoneal form* the glands may be involved alone or together with the mesenteric glands and the spleen, and from the greater enlargement of the retroperitoneal glands it may appear that the splenic enlargement is secondary. The special symptoms due to lymphadenomatous glands in the retroperitoneal space are those of pressure on adjacent structures, such as the inferior cava causing œdema of the feet and abdominal wall and albuminuria, on the bile-ducts causing jaundice, which in a case mentioned by MacDonald came on early in the course of the disease, on the spinal nerves causing pain, and on the sympathetic plexuses leading to dyspepsia, vomiting, and colic. Pressure exerted on the bowel has been associated with obstinate constipation; and periodic increase in the size of the glands, which may correspond with the bouts of fever, may account for attacks of pain in the back or the lower limbs. Pain associated with irregular fever and resistance in the upper abdomen suggested a leaking gastric ulcer, but at laparotomy the glands showed acute Hodgkin's disease (MacDonald).

The lymphogranulomatous change, when thus hidden at the back of the abdomen and impalpable, may be responsible for obscure fever, and when its character is that of the relapsing fever type the absence of enlarged glands does not justify the diagnostic exclusion of the disease (Horder[40]), but the diagnosis is very difficult, as shown in Whittington's case, in which an acute onset first suggested peritonitis, then appendicitis, enteric fever, splenic anæmia, tuberculous peritonitis, and obscure malignant disease.

Cutaneous pigmentation has been reported in association with a mass of lymphadenomatous glands around the adrenals (Nieczkowski; Fowler; B. Bramwell; Symmers), and may be due to irritation of the sympathetic or with less probability to interference with the adrenals. Lymphogranulomatous glands around the aorta may invade the dorsal vertebræ and pass through the intervertebral foramina into the spinal canal, and even lead to compression of the spinal cord and paraplegia. It is possible that some cases of herpes zoster are due to irritation of the ganglia on the posterior nerve-roots.

(3) *Gastro-intestinal lymphogranulomatosis* is a difficult subject; more cases were recorded in the days before the histological characters were established in 1902. Among Desjardins and Ford's 135 cases there was no instance of gastric or intestinal implication, but Prof. Turnbull found one case with extensive implication of the intestine among his 47 necropsies, and Steindl has recently reported nodular lymphadenoma of the gastric mucosa, the glands in the mesentery being the only other site involved. In 1904 Salaman denied that the alimentary canal was ever affected, and, indeed, that Hodgkin's disease is a pathological entity. Although it would be natural to expect that Peyer's patches and the solitary follicles would be affected, especially in cases in which the abdomen bears the brunt of the disease, and is presumably the portal of entry, this is evidently very rare now.

The cases formerly described as lymphadenoma of the stomach and intestines, such as Pitt's collection of 25 cases divided into two groups of (1) seven cases in which the lesion began in the mucous and submucous coats of the stomach and intestine and projected into the lumen, and (2) the 18 cases in which it spread from the mesenteric glands to form diffuse sheaths in the subserous coat, would now be regarded as allied to, if not examples of, infective lymphosarcoma, or lymphoblastoma, a tumour of lymphocytes, of which Graves has collected 249 examples of the intestine.

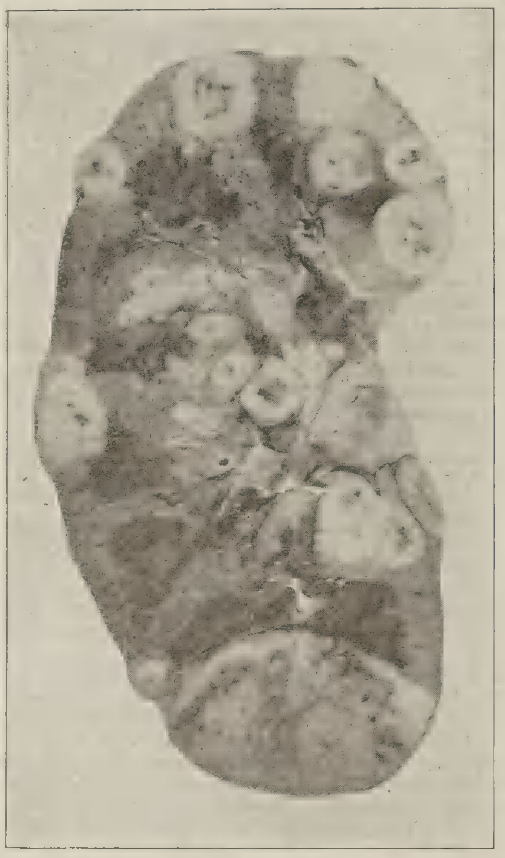
In addition to dyspepsia due to irritation of the sympathetic and abdominal distension caused by ascites and glandular enlargement, the effect of treatment by arsenic and irradiations must not be left out of account in considering the causation of gastro-intestinal symptoms. I have seen melæna six weeks after the application of radium to the abdomen, as if from a duodenal ulcer; McAlpine and von Glahn record perforation of the transverse colon in a woman aged 28 years, who had during six years been treated by X rays on 95 occasions; and Sir Thomas Horder allows me to mention a patient in whom perforation of the ileum occurred after two courses of X ray treatment to the abdomen.

(4) *Splenic form.*—The spleen is nearly always affected in cases which run their full course; Prof. Turnbull found the spleen invaded in all his 47 necropsies, and regards this as an important point in the diagnosis. Massive infiltration of the spleen by Hodgkin's lymphogranuloma with insignificant enlargement only of the lymphatic glands is infrequent, and it is very rare to find the disease entirely confined to the spleen.

Symmers described two cases; in the first[82] no glandular enlargement was detected in life, and the spleen showed the microscopic appearances of Hodgkin's lymphogranuloma, but there was no necropsy. In his second case[84] there were some palpable glands. In Wade's case no enlarged glands were detected clinically or at operation, but here again there was no necropsy. In Mellon's case there was slight enlargement of the inguinal glands. Cornwall reported a case without any disease in any glands. Dr. Krumbhaar has kindly sent me the notes of a necropsy showing lymphogranuloma of the spleen and bone-marrow, but not of the lymphatic glands. L'Esperance reported an enormous spleen, simulating a ventral hernia, with slight infection of the retroperitoneal, but not of the superficial lymphatic glands; the liver also showed invasion. Although Donhauser regarded his case of splenomegaly with sclerosed bone-marrow as a compensatory hæmatopoietic process, some later writers (Ewing) have referred to it as the splenic form of Hodgkin's lymphogranuloma. Ewing also quotes a case recorded by Kummel. In several of these cases there has been a special tendency to relapsing fever.

In some other instances after enlargement of the superficial lymphatic glands has subsided or even disappeared the spleen and liver have enlarged, and at this late stage the condition has imitated chronic splenic anæmia or the further stage with secondary hepatic cirrhosis or Banti's disease. Poynton, Thursfield, and Paterson record a case of a boy at first with some enlargement of the cervical glands, which had disappeared at the necropsy when the spleen (25 oz.) and the liver (44 oz.) were both found to be invaded.

FIG. 3.



Massive infiltration of the kidney by Hodgkin's lymphogranuloma. (By the courtesy of Dr. Carslaw and Prof. Muir.)

(5) *Hepatic form.*—The liver is affected in 50 or more per cent. of all cases of the disease, but usually this is a post-mortem, not a clinical, observation. Reference has been made to jaundice from pressure on the bile-ducts by the glands in the portal fissure, and to the possibility of mistaking an enlarged liver or apparent enlargement from glands in the neighbourhood when associated with relapsing fever for hepatic abscess. Limitation of Hodgkin's lymphogranuloma to the liver is unknown, but I have seen the organ greatly enlarged secondary to lymphadenomatous glands in the groin in one case, and at the elbow in another instance. Symmers[84] reported a case in which the liver was enormously and, except for the spleen and abdominal lymphatic glands, exclusively invaded.

(6) *The renal form.*—The kidneys occasionally show nodules of white lymphadenomatous growth, usually small in size, and in rare instances the perirenal lymphatic glands are much enlarged.

By the kindness of Prof. R. Muir and Dr. J. Carslaw, of Glasgow, I have been provided with the notes of a man, aged 26, with extensive lymphadenoma (vide Fig. 3) of the right kidney (17 oz.), which was studded throughout with whitish nodules of soft cellular tissue resembling to the naked eye secondary sarcoma, the largest being ¾ inch in diameter. The left kidney (3 oz.), apparently small congenitally, contained one or two nodules of the same growth. Microscopically the liver (47 oz.) showed diffuse lymphadenomatous infiltration of the portal canals, thus contrasting with massive invasion of the right kidney. The spleen (15 oz.) contained nodules and the retroperitoneal glands were markedly involved. The bodies of the first four dorsal vertebræ and the dura mater were invaded, and the spinal cord softened; before death the patient had become paraplegic.

Apart from a trace of albumin clinical manifestations associated with renal invasion have not attracted attention, but J. Galloway recorded the case of a man with polyuria and a protein resembling in some respects, but differing in others from, Bence-Jones's protein. The kidneys contained cysts and microscopically showed small areas of lymphadenoma.

CUTANEOUS MANIFESTATIONS.

The cutaneous manifestations of Hodgkin's lymphogranuloma are of various kinds, and raise some questions of interest. It has been estimated that 25 (Ziegler) to 39 (Cole) per cent. of the cases exhibit them in one form or another.

Pigmentation may be due to the local action of X rays, the administration of arsenic, the scratching induced by pruritus, or to nerve irritation by affected retroperitoneal glands, or possibly to adrenal disorder. Symmers's patient with acanthosis nigricans had lymphogranulomatous invasion of the cœliac plexus without any implication of the adrenals. The pigmentation may suggest Addison's disease.

The *hair* may become altered in colour; in Byrom Bramwell's patient it became lighter, finer, and more silky. Pruritus and itching may lead to perifollicular inflammation and loss of hair, but in Porter's account of a patient with almost universal alopecia no mention was made of pruritus.

Perspiration may naturally accompany the swinging temperature in the Pel-Ebstein syndrome, but it may also be associated with pruritus. The parchment-like condition due to continued scratching has been noted to cause diminution in the sweat. (Nanta and Baubru.)

Œdema of the skin may be mechanical; areas of atrophy may depend on impaired nutrition, and in rare instances hæmorrhages have been recorded; it is tempting to associate recurrent purpura, as in Weber's[94] case, with the diminution in the platelet count known to occur in the later stages; but I do not know that thrombocytopenia has been found in purpura in Hodgkin's disease.

Ætiologically the cutaneous manifestations fall into two groups, (1) the toxic, and (2) those due to invasion of the skin by the lymphogranulomatous tissue characteristic of Hodgkin's disease.

The reported incidence of *pruritus* varies; Favre considers it constant, but apparently it is a diagnostic factor of his adénie éosinophilique prurigène; his pupil Colrat found it in 11 out of 13 cases, and no doubt inquiry from the patient would increase the number of recorded instances. In Longcope's 86 histologically proved cases it was noted in 3 only; Desjardins and Ford found it in 9 per cent. of 135 similarly established cases. It is the commonest of the skin manifestations and is responsible for the next most frequent, namely, prurigo. When present it is usually an early symptom, often months before there is any glandular enlargement, and so may be regarded as scabies or analogous to the premycotic stage dermatosis of mycosis fungoides (Weber and Dove), and herein a clinical resemblance of these two conditions may be shown.

It may, however, occur after the diagnosis has become clear from the ordinary clinical picture, and then come and go, or in rare instances appear only in the terminal stage. It may be excited by stimulation of the skin by changes of temperature, X rays, or arsenic (Galloway). Its pathogeny leaves room for much speculation; on analogy it has been regarded as anaphylactic or to be toxic. Though irritation of the terminations of the sensory cerebrospinal nerves would appear an obvious explanation, it has been regarded as due to spinal radiculitis (Milian and Blum) and analogous to tabetic pruritus, and even to irritation of the sympathetic (Golay). The easy explanation that pruritus may be toxic, does not perhaps carry great weight in the light of the inconstancy of its incidence and its occasional appearance long before there are any palpably enlarged glands. But it may be that deep-seated lymphadenomatous glands provide the pruritogenic poison long before the more outlying and superficial glands are affected. The occasional occurrence of amyloid disease in Hodgkin's lymphogranuloma, of which Fabian collected 22 examples, points to the action of a powerful toxin, but there is no reason to believe that the occurrence of amyloidosis and pruritus are associated. Abnormal sensitiveness of the nervous system might be thought to play a part in the occurrence of pruritus, and Galloway's observation that arsenic, which is a nerve tonic, sometimes excites pruritus, might be mentioned to support the view that an inherent or acquired susceptibility of the central nervous system plays a part.

Pruritus is far commoner in Hodgkin's lymphogranuloma than in leukæmia, in which it is generally stated to occur. I have never seen it, and of 12 recorded examples of leukæmic pruritus it is noteworthy that 6 are cases of universal leukæmia of the skin collected by Ketron and Gay. It would be interesting to correlate the incidence of pruritus with the structural changes in the two conditions, especially whether the presence of small areas of necrosis, which are common in Hodgkin's lymphogranuloma, account by a resulting anaphylactic mechanism for the pruritus. The pruriginous papules are small-celled collections, and would appear to be purely inflammatory, and so to be distinct from lymphadenomatous invasion of the skin; but this differentiation may be far from easy in the early stage of the latter. Difficulty may also arise in distinguishing these pruriginous papules from the cutaneous infiltrations in aleukæmic leukæmia.

Among other cutaneous manifestations presumably of a toxic nature are eruptions of an erythematous, morbilliform (Webster), urticarial (MacNalty), bullous character, and universal exfoliative dermatitis. The occurrence of these different forms may perhaps be explained by differences in the resistance and susceptibility of the skin.

Infiltration of the skin by Hodgkin's lymphogranuloma, apart from extension from immediately underlying lymphadenomatous glands, is much rarer than the skin changes of prurigo. In 1924 I could collect 12 cases only. It thus contrasts with mycosis fungoides, which, indeed, has been thought by Ranvier (1869) and K. Ziegler (1911) to be the cutaneous form of Hodgkin's disease, a view difficult to harmonise with the histological appearances. The cutaneous tumours in Hodgkin's lymphogranuloma may be small or large and flat; they grow slowly and seldom, as in Langley and Cole's cases, ulcerate. As a rule, the presence of the tumours has not been associated with pruritus. As they are usually part of the generalisation of the disease they are a late phenomenon in its course.

HERPES ZOSTER.

Herpes zoster is probably more frequent in lymphadenoma than in any other disease, though it is not at all common. The questions arise, is it always due to arsenical treatment, does arsenic only render the patient more susceptible to the responsible virus, or may it in some instances be due to irritation of the posterior root ganglia by enlarged glands close to the spine? Weber's conclusion that patients taking arsenic are disposed to acute pneumonia, which is so often associated with febrile herpes labialis, is perhaps of interest in this connexion. Weber [93] has never seen herpes in Hodgkin's lymphogranuloma apart from arsenical treatment; but this has probably occurred in some recorded instances (O'Flynn; Pancoast and Pendergrass). It may appear early or late in the course of the disease, and may even recur; in a boy seen in consultation there had been three attacks. I have seen it generalise like varicella. The scars left by an attack of herpes may show up as leucodermic patches against the skin of the trunk rendered pigmented by arsenical treatment.

SYNOVITIS.

Very little attention has been paid to arthritic manifestations in Hodgkin's lymphogranuloma, and no doubt they are rare. From the two cases I have seen they would appear to be transient and not well marked.

In a man in St. George's Hospital with generalised lymphogranuloma there was œdema of the left thigh and leg from pressure and at one time evidence of considerable effusion into the corresponding knee-joint, but this had disappeared at the necropsy. A boy, aged 11 years, seen in consultation in 1923. had recurrent attacks of synovitis with considerable effusion in the left wrist and elbow, knee and ankle, and right temporomaxillary joint, followed by darkening of the skin suggesting hæmorrhage Some of the attacks were febrile, others afebrile; they subsided spontaneously; as salicylates were employed in one attack only and the heart was normal, there was no reason to regard them as rheumatic. It may be noted that he also had three attacks of zona on the right side of the chest, pruritus, and a rash. The question arises whether toxæmia due to liberation of a protein from X ray exposures, which had been freely employed, were responsible for the synovitis.

As Hodgkin's lymphogranuloma appears to invade the bone-marrow in about half the cases, it might, on the analogy of tuberculosis, have been expected that the joints would be prone to invasion. On the other hand, it may be pointed out that myeloid leukæmia, which, according to Symmers,[84] is fundamentally related to Hodgkin's disease, does not cause arthritic manifestations.

SKELETAL INVASION.

Lymphadenoma in bone was described by Weber [88] some years before the histological features of lymphadenoma were established; his case would appear to be one of multiple myeloma. Invasion of bone by lymphadenoma is now generally recognised.

Among 14 cases Symmers found it in seven, or 50 per cent., and describes two changes which may be present at the same time, (*a*) hyperplastic compensation in response to demand for more blood corpuscles, which he regards as identical with that in chronic myeloid leukæmia, and (*b*) invasion by lymphogranulomatous tissue. Among 39 necropsies at the London Hospital Prof. Turnbull found the bone-marrow invaded in 19, or 49 per cent., the femur and the lumbar vertebræ being the parts of the skeleton most often affected; from comparison of the sites of the glandular groups most enlarged, and therefore presumably primarily affected, on the one hand, and the bones affected on the other hand, he obtained results which suggest that the femur is invaded through the blood-stream, and that the lumbar vertebræ are involved as a result of direct spread from the retroperitoneal glands.

On the question whether the changes in the bone-marrow are part of a widespread reaction to the stimulus of the unknown virus or whether they are secondary, in the same way as generalised tuberculosis is, to infection from a primary focus, there may be room for discussion. Prof. Turnbull concludes that they are secondary. It is noteworthy that spontaneous fracture of bones, which may occur in secondary carcinoma and in endosteal sarcoma, is not known in invasion of bone by Hodgkin's lymphogranuloma. Bence-Jones's proteinuria, which is a feature of multiple myeloma, appears to have been recorded in one case only of Hodgkin's disease (Galloway).

PARAPLEGIA.

In rare cases paraplegia occurs in the course of Hodgkin's disease; Weber[92] refers to 12 examples, in six of which a necropsy was performed. The paraplegia may apparently be due to: (1) Pressure on the spinal cord by lymphogranulomatous growth gaining entrance into the vertebral canal either through the intervertebral foramina or from the infiltrated vertebræ; this form of pressure paraplegia appears to have occurred in five of Weber's cases. These cases would probably be those with retroperitoneal localisation of the disease, in which sarcomatous change has supervened. (2) Pressure on the nerve roots; in a case of W. Hale-White[92] this was exerted inside the vertebral canal. (3) Myelitis and acute meningitis without any evidence that the spine or dura mater had been invaded by the lymphogranuloma (Allan and Blacklock); in view of the rarity of paraplegia in Hodgkin's disease the myelitis may well have been independent of that disease except in so far as it reduced the patient's power of resistance and so favoured the infective cause of the lesion in the central nervous system. (4) It would be natural to expect that arsenical neuritis might be responsible for paraplegia; I have seen one case, recorded by Carlill, which might bear this interpretation.

DIAGNOSIS.

The distinction from other forms of glandular enlargement, tuberculous, leukæmic, chronic inflammatory, and sarcomatous, and from other pyrexial states would, if systematically considered, occupy much space, and a few points only will be touched on.

The Value and Fallacies of Biopsies.—From the difficulties of clinical diagnosis a dogmatic opinion is uncertain and often unwise until a gland has been removed and found to show the characteristic histological changes. Unfortunately a gland excised from a case of Hodgkin's lymphogranuloma does not always show the lesions; its enlargement may be due to simple non-specific inflammation or to compensatory hyperplasia. According to Prof. Turnbull the histological changes are best seen in glands which are very hard and from contraction not necessarily enlarged, and not very infrequently the microscopical report cannot go further than "lymphogranuloma, possibly Hodgkin's, but histological characters are not definite." In contrasting the value of microscopic examination of excised glands Webster found that it gave much more correct diagnostic results in Hodgkin's lymphogranuloma than in cases finally shown to be lymphosarcoma.

Diagnosis from Sarcomatous Lymphomas.—The greatest difficulty is the clinical differentiation of Hodgkin's lymphogranuloma from lymphosarcoma and the closely allied malignant lymphocytoma composed of small lymphocytes, and from endothelial sarcoma. I have seen cases apparently running the clinical course of Hodgkin's lymphogranuloma show these histological appearances finally; the question arises whether, as probably most would consider, these conditions have existed from the start, or whether they have supervened as the result of Hodgkin's lymphogranuloma. Is there any evidence of this change, such as a biopsy early in the course of the disease showing the appearances of Hodgkin's disease, and later a necropsy proving the sarcomatous nature? It does not appear to me that the therapeutic test of X ray exposures helps in distinguishing them. I have personal knowledge of what appeared to be Hodgkin's disease, but turned out to be malignant lymphocytoma reacting in a wonderful manner, life being prolonged for three years after an early termination seemed inevitable, to Dr. W. B. Coley's personal treatment by the mixed toxins of erysipelas and *Bacillus prodigiosus* and massive doses of radium.

Undetermined forms of glandular enlargement, such as those spoken of as infectious mononucleosis and glandular fever, may, though of comparatively short duration, give rise to difficulty in diagnosis. Infectious mononucleosis according to Sprunt and Evans presents a slight leucocytosis with some increase in the large mononuclear-transitional cells and many pathological lymphoid forms.

Cases of aleukæmic leukæmia—namely, leukæmia in an aleukæmic phase, and cases which come under Bunting's heading of lymphoblastic aleukæmia, can hardly be differentiated from Hodgkin's disease except by histological examination of an affected gland.

Under the heading of *splenomegalia lymphatica hyperplastica* Brill, Baehr, and Rosenthal describe a generalised lymph follicle hyperplasia of the lymphatic glands and the spleen with a normal blood count and readily curable by X rays. The spleen is enormously enlarged and shows giant Malpighian bodies the size of a barley grain $\frac{1}{8}$ in. in diameter, and almost entirely composed of endothelioid or reticular cells. The follicles of the lymphatic glands are greatly enlarged due to cells of an endothelioid or reticular type, like those seen in the germinal centres of lymph follicles, especially in children. The appearance is said to be quite different from that of ordinary follicular hypertrophy and of lymphatism. Before the curative effect of X rays was found out, splenectomy was performed in two out of three cases recorded; in one it weighed 56 oz. (1800 g.). The cause of this condition was not determined, whether from toxic influence within or without the body; they quote Kusczinski as having produced generalised lymphoid hyperplasia in mice by special diets. How often cases of this kind come to hospital, and after being diagnosed as Hodgkin's lymphogranuloma are treated with X rays and arsenic and are then lost sight of it is impossible to say; a case of general hyperplasia of all the lymphoid tissues except the thymus with a leucocyte count of 23,235 (polymorphonuclears 82 per cent.) was reported by C. H. Miller.

I have twice seen a symptom-group which may imitate lymphadenoma—namely, a "hypernephroma" of the left kidney or adrenal body producing a tumour imitating splenomegaly and glandular metastases above the left clavicle; from the fever described in necrotic hypernephromas (Symmers[84]) the resemblance might be increased.

PROGNOSIS AND TREATMENT.

The universal fatality of this disease, which in other respects has many resemblances to tuberculosis, may perhaps be correlated with the much less marked tendency of the lesions to undergo necrosis and fibrosis, as if the unknown cause were more persistent, though not necessarily more virulent, and the resisting powers of the body less able to bring the disease to an end. The absence of extensive necrosis and of caseation might suggest that the process is less acutely virulent.

The duration of symptoms varies; acute cases lasting a few weeks are rare, and the suspicion may arise that from the presence of internal glandular disease they are not so acute as the duration of obvious signs, due to generalisation, would suggest. When the primary site is in the thorax or abdomen and extension later occurs to superficial glands, the course may, when calculated from their detection, be very short; the primary enlargement, especially in the chest, may, owing to the adaptability of the viscera, remain latent for a long time and be detected by skiagraphy only.

Prognosis as to duration of life depends on treatment by arsenical preparations and irradiations, for there is not any evidence that, as in tuberculosis, a spontaneous cure occurs. The effect of arsenical preparations is at first most successful; but relapses occur, and eventually the drug fails to control the disease, as if the unknown virus became arsenic-fast or the morbid process underwent some change. The same appears to be true with regard to the radiations of X rays and radium; but in most exceptional instances this does not hold good; Schniffner recorded the case of a woman who for 11 years was benefited by X rays. It has even been suggested that X rays may lead to generalisation of the disease (Weber[95]), just as it has sometimes appeared to do in carcinoma. Simmonds and Benet prefer radium to X ray treatment, and urge that it should be applied on all the lymphatic areas in the body and not only on those obviously affected.

Vaccines of the diphtheroid organism have not proved successful, but Bunting mentions trials with an immune serum (to this organism). Success has attended the treatment, by Dr. W. B. Coley, of New York, of Hodgkin's disease by repeated injections of the mixed toxins of erysipelas and *Bacillus prodigiosus* and of massive doses of radium; of this I have had much recent information from him.

Surgical opinion has long been adverse to removal of lymphadenomatous glands on account of the difficulty of complete extirpation and of the frequency of similar intrathoracic disease. Symmers [84] throws out a warning of the danger of secondary infection as a result of excision of the inguinal glands. Removal of infective foci, such as the tonsils, and free surgical extirpation of the disease in an early stage has been advocated by Bunting and Yates on the lines of the Halstead and Crile operations for the lymphatic glands in mammary carcinoma. But the cases are not necessarily analogous, for the primary growth in the mamma is removed, whereas in lymphadenomatous glands in the supraclavicular fossæ and neck the thorax or abdomen may be the primary focus.

BIRMINGHAM HOSPITAL SATURDAY FUND.—This fund has just distributed £25,000 from this year's collection to the voluntary hospitals and nursing societies of the city. The grant to the General Hospital amounts to £7500; to the Queen's Hospital, £5650; to the Children's Hospital, £2100; to the General Dispensary, £1750; and to the Women's Hospital, £1600.

WESTERN OPHTHALMIC HOSPITAL.—It is reported that the condition of this hospital, which is situated in the Marylebone-road, is growing steadily worse. It is housed in an old building known to date back more than a century and a half, which, notwithstanding struts and tie-rods, continues to crack, and occasionally a ceiling falls. The house, moreover, is extremely crowded and inconvenient. The staircase from the men's ward to the operating theatre is so "narrow, rickety, and crooked" that an ambulance cannot be taken up or down, and patients have to climb the stairs; upon occasion operations upon men have to be performed on a screened bed in the women's ward. The pathological laboratory is a small underground apartment, and there is only one bathroom for women patients, nurses, maids, and matron. A new building will cost £40,000, towards which £14,000 has been accumulated. As regards current expenditure the hospital pays its way.

An Address

ON THE

CASE FOR THE UNBORN CHILD.

Being the David Lloyd Roberts Lecture delivered at St. Mary's Hospital, Manchester, on Nov. 17th, 1925,

BY THOMAS WATTS EDEN, F.R.C.S. EDIN.,
F.R.C.P. LOND.,
CONSULTING OBSTETRIC PHYSICIAN, CHARING CROSS HOSPITAL, LONDON.

(Concluded from p. 1158.)

THE EFFECTS OF ALCOHOL ON THE FŒTUS.

I DO not wish to raise the vexed question as to whether or not alcohol is really a dietetic substance. There are, however, some considerations in regard to it which cannot be ignored in any review of the possible effects of maternal diet on the fœtus. There is a very ancient belief that children begotten during drunkenness are liable to be deformed. This belief found its expression in pagan mythology, for Vulcan, the deformed son of Jupiter and Juno, was begotten when both parents were intoxicated; his deformed condition so angered his mother that she cast him into the volcano, where he laboured for ever at the forges of the gods. The tradition has survived, and, unlike the great majority of such myths, it appears to have a very good chance of being eventually established as a scientific fact. Already, in the opinion of several authorities, the point has been proved as nearly as such a point ever can be proved by clinical observation.

In considering the effects of alcohol, the first point to bear in mind is its great diffusibility. It becomes rapidly absorbed directly from the stomach and soon becomes equally diffused throughout the fluid and solid tissues of the body. It passes readily through the placenta and can be detected in the umbilical blood. Further, though readily diffusible, alcohol is not quickly eliminated; strictly speaking it is not eliminated at all, but gradually destroyed by oxidation in the tissues of the body. Mellanby showed that after only a small dose of alcohol had been drunk it could be detected in the blood for 19 hours. I do not think it can be disputed that alcohol drunk by the mother will pass into the fœtal circulation, that it will be present at any given moment in approximately the same degree of concentration in both mother and child, and that the child will be subjected to its influence for a comparatively long time, owing to the tardiness of its disappearance from the tissues.

It would not be right to deduce from this that a pregnant woman who takes alcohol as a beverage is thereby doing harm to her child. Physiologists are still uncertain whether it can truly be said that the action of occasional doses of alcohol is in any degree deleterious. They are unanimous that the frequent taking of alcohol, so that the tissues never get the chance of completely freeing themselves from it, is harmful in certain definite respects. But if the dose is not too closely repeated, so that the first is disposed of before the second is taken, the tissues can completely recover from its effects and suffer no harm. The habit of frequent "nipping" during pregnancy cannot fail to bring the fœtal organ and tissues under the sustained influence of alcohol, from which they never get the chance of freeing themselves by completely oxidising it.

It is notorious that a very high infant mortality occurs among the children of alcoholic parents. This is in great part due to the unfavourable home conditions under which these children are reared; poverty, neglect, bad feeding, and insanitary surroundings all tend to swell the number of deaths in infancy. It is, however, probable that the children of alcoholic parents are handicapped from the start by birth deficiency in respect of vigour and of powers of resistance. It is notorious that the chronic alcoholic adult is not a "good subject" either for surgical operation or for acute illness. If the child of a chronic alcoholic mother has been subjected to the constant influence of alcohol throughout the whole period of intrauterine development, it is hardly conceivable that it can escape without some degree of damage.

Up to this point what has been said had reference mainly to the alcoholic mother and the injury she may do to the child she is carrying. There is, however, a further aspect of the matter to which attention should be drawn. A good deal of experimental work has been done in recent years to determine the effect upon their offspring of subjecting animals, both male and female, before mating, to the effects of the fumes of alcohol, continued for a long period. As so often happens, the results obtained with different animals are widely divergent. Pearl,[14] an American observer, worked with fowls, subjecting them to the fumes of alcohol before laying, and also their eggs to the same fumes during incubation. In order to save time and avoid confusion I shall not quote his results, for the reason that reproduction in birds (oviparous) is so widely different from that which obtains in man, that the greatest caution should be observed in applying them. Stockard[15] has carried out a series of experiments with guinea-pigs which have been continued for 12 years, and cover many generations of animals. His method was to expose the guinea-pigs to a daily inhalation of alcohol fumes up to the point of intoxication. He found that very marked results were observed in the young of the alcoholised animals. He found, in brief: (1) that the fertility of the animals was diminished; (2) that the young were deficient in vigour and in power of survival after birth; (3) that a high proportion of developmental defects occurred; (4) that these defects were practically confined to the central nervous system and the organs of special sense; and (5) the defects were transmitted, in some instances, to the third generation, although only the original grandparents had been subjected to the influence of alcohol.

As regards the vitality of the young of alcoholised parents he found that only 46 per cent. survived, the survival rate for normal animals kept under identical cage conditions being 78·5 per cent. In the alcoholised animals deformities were found in 5·23 per cent. of the young, while they never occurred in control animals, unless they were closely inbred. In addition to the developmental deformities, considerable numbers of dwarfish, undersized young were found in the litters of alcoholised animals, while they were very rare with normal animals. The effects of alcohol on the male are much more marked than on the female; a certain number of normal females, after mating with normal males, were subjected during pregnancy to the influence of alcohol without any injurious effect on the young. Stockard opined, however, that evil results would have manifested themselves if the treatment with alcohol had been more prolonged.

Stockard attributed the results he obtained to a toxic effect of alcohol on the germ-plasm, producing structural alterations capable of transmission through several generations. This effect is much more marked upon the male than on the female. He did not think that alcoholisation of the fœtal environment had much to do with the effects produced upon the young.

How far these results can be held to be applicable to man cannot at present be settled. It is obvious that where alcohol is given by the method of inhalation its degree of concentration in the blood of the animal is never so high as when alcohol is given by the mouth. In these respects the experiments do not reproduce the ordinary conditions of alcoholism in man, yet the effects produced upon the nervous system of the young resemble in many respects those seen in man.

That alcoholism in the parents is one of the most important predisposing causes of mental deficiency (amentia) and epilepsy all the authorities on this subject are agreed. The percentage of cases of amentia in which an alcoholic history can be obtained is put by different observers at rates varying from 4 per cent. to 40 per cent., which I think sufficiently indicates the difficulties of such an inquiry. We have no precise observations as to the difference, if any, between the children of alcoholic and non-alcoholic parents as regards birth weight and general vitality. The information we do possess, however, is, I think, sufficient to lay upon us the duty of advising abstinence from alcohol during pregnancy, and of pointing out clearly the possible deleterious effects on the child of over-indulgence.

EFFECTS OF MATERNAL DISEASE.

When we come to consider the case of the fœtus in utero which is subjected to the influence of maternal disease, a field is opened up which is so wide that it will only be possible to glance at the subject. There are no national statistics of the causes of antenatal death, and such information as we can gather about it is gleaned from the very valuable reports which most of our lying-in hospitals now publish. There are also some foreign statistics of which we can make use.

Couvelaire[16] has recently published data taken from the records of the Clinique Baudelocque in Paris, over a series of 20 years, 1890 to 1919 inclusive. During this period out of 57,642 births, there were 1769 cases in which the fœtus had perished before the onset of labour, equivalent to a stillbirth-rate of 3·0 per 100 births. The causes of death were stated as follows :—

Syphilis..	653	Various ..	175
Toxæmias	346	No cause discovered	572

Syphilis.—It appears, therefore, that in this series more than 50 per cent. of the fœtal mortality could be traced to syphilis and to pregnancy toxæmias taken together. The number of syphilitics was probably in excess of the figure given, for a proportion of those classed as "undetermined" should in all probability be included. Couvelaire further states that since the rule has been introduced at the Clinique to practise the Wassermann test in all cases systematically, the proportion of syphilitics has risen to over 50 per cent. of the whole. It must be recollected that these are statistics of fœtuses which died in utero before the onset of labour. Unfortunately the English lying-in hospitals furnish no comparable figures regarding the proportion of fœtal deaths due to syphilis. Probably many cases are overlooked in this country because the Wassermann reaction is not in routine use. Apart from the incomplete returns of the hospitals, the only English data that we have bearing on the frequency of syphilis in the fœtus are those furnished by Eardley Holland in his recent work on the Causation of Fœtal Death, carried out under the auspices of the Ministry of Health. In his examination of 300 dead-born fœtuses only 42 cases of "proven" and six of "probable" syphilis were found, making together—i.e., including the "probables"—16 per cent. of the whole as due to syphilis. These figures are not really comparable to Couvelaire's, because in the latter the diagnosis was established not only by examination of the fœtus and placenta, but also by clinical examination of the parents, including the Wassermann reaction. Even when allowance is made for these divergences, it would appear than in the practice of lying-in hospitals syphilis is less common in London than in Paris. Probably a large proportion of our syphilitic mothers go to the Poor-law infirmary for their confinement rather than the lying-in hospitals.

At the same time it may be pointed out that our lying-in hospitals, and especially the antenatal clinics, have the opportunity of rendering a great public service by instituting a strict search for latent syphilis in women with a bad obstetric history. Modern methods of antisyphilitic treatment have in no department achieved more striking successes than in the prevention and cure of congenital syphilis. If all syphilitic mothers could be adequately treated during pregnancy the congenital syphilitic child would disappear, and the part which obstetricians could play in this work is clearly a most important one, for even if the hospitals have not facilities for treatment they could make the diagnosis and see that the patient was treated elsewhere. Couvelaire has published his results of antisyphilitic treatment at the Clinique Baudelocque during the years 1920–22. In 256 cases treatment was applied to the mothers as follows :—

1. Only during the later months ; these women had a fœtal mortality of 30 per cent.
2. Throughout pregnancy ; these had a fœtal mortality of 15 per cent.
3. Before and during pregnancy ; these had a fœtal mortality of 3 per cent.

In contrast there were 218 untreated cases of recent syphilis which gave a fœtal mortality of from 65 per cent. to 70 per cent.

Results almost as striking as these have been obtained in London by Mr. John Adams at the V.D. Clinic for Syphilitic Mothers, established under the auspices of the Metropolitan Asylums Board.

INTRANATAL PERIOD.

Let us turn now to the causes of stillbirth as shown in the lying-in hospitals, and in dealing with these data we must first exclude miscarriages altogether ; some of the hospitals do not admit these cases at all, and none give details bearing upon the causation of miscarriages, so that they are of no use for our present purpose. Next we must exclude cases in which the fœtus died in utero before the onset of labour (antenatal death), for in these circumstances the fœtus could not have been saved except possibly by antenatal treatment. There will then remain only those deaths which occurred during the birth process (intranatal death). We shall also, in connexion with certain points, have to include deaths in the neonatal period.

Antenatal death is the result of pathological processes, and can generally be recognised by the macerated condition of the fœtus when born ; a few may escape recognition and be included in the intranatal class if death occurred too recently to allow of the occurrence of maceration. Intranatal death is in the main attributable to what we may call, using the term in a broad sense, birth-traumatism. Birth-traumatism is also responsible for a considerable number of neonatal deaths, the injury received in the birth process not being immediately fatal. The figures quoted from the Clinique Baudelocque include apparently only the first class ; we have no information as to the number of deaths which occurred during birth—i.e., intranatal death.

In considering the number of fœtal deaths during labour in our own lying-in hospitals we must further take account of the fact that these hospitals receive a disproportionately large number of serious maternal complications in which the risks to the child are very high. Such conditions as ante-partum hæmorrhage and eclampsia figure largely in the hospital returns as causes of fœtal death. Further, a certain number of dead infants are delivered by craniotomy. I propose, therefore, to give first of all the gross rate, A, including all cases of dead-born children; then a corrected rate, which we may call B, obtained after deducting all cases returned as macerated; then a third rate, C, which has been obtained by deducting cases of craniotomy, of ante-partum hæmorrhage, and of eclampsia from rate B. (vide infra). The addition to rate C of neonatal deaths, directly traceable to injury, will give us the true intranatal death-rate. It will be recollected that the stillbirth-rate for the whole country is 3·3 per cent., and the dimensions of rate A, in most of the hospitals, is unexpectedly high. The rate is not much reduced by the exclusion of macerated fœtuses, except in the case of one hospital, and it will be seen that rate B is, on the average, less than 10 per cent. below rate A. The exclusion of the various maternal complications, however, cuts rate B down to little more than one-half in the case of all the hospitals alike. The figures shown in the table have been calculated for an average of five years in all but No. 6, for which only three years were available.

Fœtal Death-rate.

Hospital: 5 years' average.	Gross rate.	Corrected rate.		Hospital: 5 years' average.	Gross rate.	Corrected rate.	
	A.	B.	C.		A.	B.	C.
	%	%	%		%	%	%
1	15·7	14·7	8·9	4	12·0	9·9	5·3
2	12·2	11·5	5·7	5	5·9	5·4	3·1
3	12·9	11·7	5·6	6	5·38	—	—

The difference between the fœtal mortality-rate of the first and last hospitals on the list is surprising. Hospitals 1 to 4 are all situated in great industrial centres; Nos. 5 and 6 are in London and their patients are drawn from a class which is engaged almost entirely in domestic work and business, or light factory occupations. There are no heavy industries in the parts of London served by these hospitals. The rate A figures for hospitals 2, 3, and 4 are so nearly identical that they carry conviction of their reliablity, and I think we may take it that they indicate that the loss of fœtal life is considerably higher in an industrial population than in what, for contrast, we may call a non-industrial population. We cannot enter into any consideration of what these causes may be, but the point is deserving of further inquiry.

Rate C is that obtained when all possible allowance has been made for the special difficulties of hospital work by the exclusion of all the graver complications of labour. Except in the case of one hospital, the rate is far above the national stillbirth-rate, in which all these complications are, of course, included. In the case of hospital 1 the national rate is nearly trebled. This is a result which I had not anticipated, and I would ask you to note that in regard to rate C, as well as rate B, hospitals 2, 3, and 4 give an almost identical figure, while hospital 1 is more than 50 per cent. higher than any of them, and nearly three times as high as hospital 5. Does this imply that the infants of parents living in great industrial centres show a diminished vitality as compared with those born in non-industrial centres, which renders them less able to bear the stress of labour? No answer can be given to this question either, but one or two points may be cleared up by looking into the recorded causes of death in Group C. They fall into three main groups: (1) birth-traumatism, (2) prematurity, and (3) congenital defects and diseases. A certain number remain which are difficult to classify.

Not all the hospitals furnish information sufficiently detailed for our purpose, but I have been able to examine an aggregate of 561 stillbirths falling into rate C, with the result shown as follows:—

Of 561 stillbirths falling under rate C—

48·7 per cent. were due to trauma.
8·3 per cent. were due to prematurity.
4·9 per cent. were due to defects and diseases.

The remainder, amounting to a little more than one-third, were unexplained, or due to a variety of conditions which do not lend themselves to classification.

It appears, then, that if we exclude cases in which labour was complicated by serious maternal complications, nearly half the fœtal mortality in the lying-in hospitals whose reports were examined is due to birth-traumatism. Of course, not all the cases included under this heading showed recognisable signs of injury; in a small proportion death was returned as due to "stress of labour" or some equivalent term. There is no doubt that some infants appear to suffer severely from the effects of what we should clinically call a normal labour; the transit of the child through the maternal passages will no doubt always carry with it risks the extent of which depends in part upon that incalculable factor the endurance of the child.

A large number of deaths from traumatism occurred in premature children whose power of resistance to shock is very low in comparison with the mature child. The two causes of injury and prematurity are closely related and it will be interesting to look a little more closely into the question of premature births.

The accompanying table brings out two or three points which are of some importance. The second column gives the proportion of births, which were premature in three different hospitals.

Premature Births.

Hospital.	Premature birth-rate.	Stillbirth-rate.		Neonatal death-rate.	
		Premature.	Mature.	Premature.	Mature.
	%	%	%	%	%
3	32·9	21·21	4·30	15·29	1·10
5	10·76	25·29	3·66	17·46	3·47
6	12·24	20·80	3·17	13·50	0·55

In hospital 3 nearly one-third of the children born in the hospital were premature; this hospital, as I have said, serves a large industrial centre. In the case of hospitals 5 and 6 the proportion is 10 per cent. and 12 per cent. respectively. All the hospitals serving industrial districts show about the same premature birth-rate as hospital 3. This table certainly suggests that women engaged in industrial work are unable to carry their children to term in anything like the same proportion as those engaged in lighter occupations. You will recollect that a somewhat similar observation was made by Pinard many years ago in Paris. It is impossible to pursue this point any further, but it also appears to be deserving of more extended inquiry.

Column 3 of this table shows the comparison between the proportion of premature and mature babies which are stillborn, and it is not surprising to find that the premature stillbirth-rate is from five to seven times higher than the stillbirth-rate for mature babies. This is partly accounted for by the fact that the greater number of fœtuses born macerated are premature; from the hospital reports I should judge the proportion to be about 60 per cent. The most important factors, however, are that maternal complications are more frequent in premature labour, and that even in their absence the premature fœtus is less able to endure the stress of labour than is the mature one.

Column 4 compares the chances of survival of premature and mature babies under the same hospital conditions. Here the comparison is enormously to the disadvantage of the premature baby. The neonatal death-rate of the prematures does not vary greatly in the three hospitals, and may be put at 15 per cent. The death-rate of the mature infants varies widely from one-fifth to one-twelfth of the premature rate. The figure of 3·47 for hospital 5 was due to exceptional circumstances which prevailed during two of the five years under review, and does not truly represent the average for that hospital. But between hospital 3 and hospital 6 there is a difference of 100 per cent. in favour of the latter. I must not comment on these figures for mature babies, except to suggest that the neonatal death-rate of some of our lying-in hospitals appears to be capable of improvement. I should like further to point out that we badly need a follow-up system for our premature infants; it is important that we should know how many of those who leave the hospital alive actually survive the first three months of life. We ought to know this because to estimate the results of induction of premature labour at the end of the first month is in all probability to present the results in an unduly favourable light.

I think I have said enough to show that from the point of view of life insurance the premature baby is a bad risk. In view of this fact we must recollect that a certain proportion of premature labours are deliberately provoked by the obstetrician for one reason or another. Only those are suitable for examination which appear in the hospital reports as cases of pelvic contraction or of "disproportion," and I have collected the results of this procedure from three hospitals, which give full data. These results comprise 384 cases of induction, and show an average combined intranatal and neonatal mortality of 14·3 per cent.; in the individual hospitals the rate varied from 15·5 per cent. to 9 per cent. It is to be recollected that these are picked cases in which the general condition of the mother and the child was ascertained to be good before induction. The infant deaths are due in practically every case to some form of trauma, and the only thing that can be said about it is that if induction for disproportion cannot be carried out without an infant mortality of 14 to 15 per cent., it is time that it disappeared from obstetric practice. There is much truth in Ballantyne's contention that the premature infant is "partly a fœtus and partly a new-born child . . . in it we see neonatal physiology hampered in its action by persistent fœtal conditions." It is therefore only right that we should not make ourselves responsible for bringing infants into the world in this unfit condition unless there are sound reasons for so doing.

It will be, of course, admitted that the number of induced labours is relatively small, and that the bulk of premature births are due to the maternal complications of pregnancy which we have referred to. There is also, as we have seen, some evidence that social and industrial conditions may also be concerned, and this evidence may be shortly summarised thus:—

(*a*) Pinard showed that women admitted to hospital during the latter part of pregnancy carried to term in larger proportion than those who continued at work.

(*b*) Darwall Smith showed that premature births were four times as frequent in women with bad nutritional conditions than in those of average nutritional conditions.

(*c*) The English lying-in hospitals serving industrial districts with a large factory population show a proportion of premature births three times as high as London hospitals serving districts with a relatively small factory population.

BIRTH TRAUMATA.

We must now go back for a moment to the matter of birth injuries; you will recollect that we saw that traumatism and prematurity were the two chief causes of death in class C of our fœtal mortality table. We now want to see what direct evidence we have of the occurrence of birth traumata. The premature infant suffers severely because its vitality is low. On the other hand, the postmature or oversized infant may suffer severely because its bulk increases the mechanical difficulties of expulsion. Many normal-sized infants delivered by the natural forces alone arrive in a condition of profound shock from which, however, it is true, they practically always recover; their condition is, however, clearly the result of trauma. And further, a certain number of healthy infants die during the birth process without subsequently showing any injury to which death could be attributed. These deaths are probably occasioned by the infant's inability to withstand the stress of labour. The great proportion of intranatal deaths, however, are due to injury inflicted upon vital organs during birth. It is impossible to enter at all fully into this matter, but I want to try to form some idea of the extent to which fœtal deaths can be traced to this cause.

Herbert Spencer, in 1891, drew attention to the occurrence of visceral hæmorrhage in stillborn children, and Eardley Holland in his recent well-known work found evidence of intracranial trauma in 5 per cent. of the stillbirths he examined. Not all the lying-in hospitals give details from which an estimate can be formed, but, from the records of two hospitals, I have collated a series of 561 deaths under corrected rate C—i.e., after deduction of macerated cases, cases of craniotomy, ante-partum hæmorrhage, and eclampsia—and in 272 cases death was attributable in whole or in part to injuries received during labour. In addition 37 infants which were born alive died in hospital from similar injuries. The total loss of infant life from birth injuries was, therefore, 309, which exceeds 50 per cent. of the stillbirths and corresponds to a rate of about 4 per cent. of the total infants born in the hospital. When it is remembered that we are speaking now of infants born under conditions presenting no special difficulty, I think it must be admitted that the death-rate from injury is high enough to give us a good deal of concern.

With a view to tracking the causes of this heavy mortality from birth trauma, I have looked into the results attending delivery by forceps in the hospitals. It is to be expected that the great proportion of deaths from head injuries would occur in forceps cases, although this is not shown in the reports. The forceps results from three hospitals have been taken out for five years in each case, and all cases of craniotomy, of eclampsia, and of ante-partum hæmorrhage have been excluded.

Hospital.	Total cases.	Total fœtal and neonatal deaths.	Rate per cent.
X	940	116	12·3
Y	291	36	12·3
Z	516	155	30·0

The mean rate for the three hospitals is therefore 17·5 per cent., on a total of 1747 cases.

The forceps rates for each hospital—i.e., the percentage of cases in which forceps was applied—showed no great differences, for they were respectively 10·4 per cent., 8·6 per cent., and 9·7 per cent.

There is one further consideration which should not be overlooked—viz., that in a proportion of the cases unsuccessful attempts to deliver with forceps had been made previous to admission, sometimes in the hospital district, sometimes by independent medical practitioners. In such cases injury may have been sustained by the child before admission to hospital. In the case of hospital Y, the records permit of such cases being deducted, and the result is to reduce the number of deaths to 31 and the death-rate to 10·8 per cent. The other two hospitals do not make any mention of such cases.

It is not only in forceps cases that these injuries occur; they may, of course, occur in breech labour, and sometimes in clinically normal labours.

The low maternal mortality-rate of our lying-in hospitals is a source of great gratification to us all, but our methods of delivery have not yielded equally satisfactory results from the point of view of the safety and interests of the child. The loss of infant life is high, and we should like to feel that not in one particular but in all respects our lying-in hospitals are a model and an example of British obstetric practice. Where improvement is called for we look to the hospitals to take the lead.

I have now come to the end of what I am conscious is but a very imperfect review of the conditions which affect the fœtus during intrauterine development, and the risks to which it is exposed from maternal disease, from maternal hardship and privation, and from the rough usage of the birth process. I had hoped when I began to consider the subject that I might, in addition, lay before you a few suggestions as to the lines upon which we might strive to diminish our heavy fœtal mortality, and to ensure the arrival of our new-born in a condition of full development, uninjured by the birth process, and with an unobscured prospect of survival. The task was, however, too great for me, and I shall have to await another opportunity of ventilating this important question.

THE BEHAVIOUR OF THE DIABETIC TOWARDS CIRCULATING GLUCOSE.

BY H. S. PEMBERTON, M.B., CH.B. LIVERP.,
M.R.C.P. LOND.,
PHYSICIAN TO THE NORTHERN HOSPITAL, LIVERPOOL;
AND
L. CUNNINGHAM, M.B., B.C. CAMB.,
M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE HOSPITAL.

THE relationship existing between glucose in flowing blood and glucose in the tissues is largely an expression of the variations in the factors of supply and demand. In the diabetic other factors appear to present themselves, and so much have we been impressed by the altered relationship which occurs in the diabetic that we have attempted to study some aspects of diabetic metabolism—together with the action of insulin—entirely from this point of view.

The simplest method of studying this relationship—in so far as blood and muscle are concerned—appears to lie in the simultaneous determination of glucose values in arterial and venous blood. The earliest work of this nature seems to have been done by Claude Bernard [1] (1877), MacLeod and Fulk [2] (1917), and subsequently by Henriques and Ege [3] (1921), by McCormick and others [4] (1923), by Cori, Cori, and Goltz [5] (1923), by G. E. Foster [6] (1923), by Pemberton and Cunningham [7] (1924), by Lawrence [8] (1924), and by Koopman [9] (1924).

In our work arterial blood was obtained from the radial artery, from the finger tip (for serial investigations), and from arteries bleeding during surgical operations; radial and finger blood have been shown by Foster [6] to possess identical amounts of glucose under all conditions, an observation which we have confirmed. Venous blood was obtained from the median basilic vein. Both procedures were carried out as nearly as possible together, the samples were oxalated, and estimations were made at once by the method of Folin and Wu.[10] Values of glucose and of substances chosen for controls are expressed in milligrammes per 100 c.cm. of blood. Emotion arising from pain, fright, &c., appeared to have no influence on either arterial or venous values.

TABLE I.

No.	Date in 1924.	Conditions.	Urea.		Glucose.		Chloride.		Phosphate	
			A.	V.	A.	V.	A.	V.	A.	V.
1	7/2	Ether 15 min., fasting.	13	12	110	100	487	463	—	—

3	15/2	50 min. p.c.	10	11	86	79	425	412	4·3	4·2
4	18/2	¾ hr. after 50 gr. glucose.	12	12	260	177	460	460	5·62	5·6
5	21/2	Diabetic fasting 5 hr.	22	20	300	214	—	—	—	—
6	22/2	2½ hr. p.c.	45	46	120	120	494	502	11·7	10·5
7	26/2	30 min. after adrenalin and glucose.	13	12	231	200	450	440	5·0	5·0
8	3/3	Glucose and 6 units of insulin.	12	12	222	177	518	530	3·8	3·6
9	21/3	Diabetic 3 hr. p.c.	—	—	300	288	490	496	6·0	5·9

As it might be supposed on a priori grounds that such factors as circulation through the lungs and velocity of flow might themselves determine the difference between arterial and venous concentration of glucose, and might thus invalidate deductions drawn from presumably specific causes, we found it necessary to use controls. As will be shown in Table I., controls indicate that these constant physico-chemical factors exert little or no influence, contrary to the expectation of MacLeod.[11] The substances used as controls and estimated together with glucose were: urea by the method of Van Slyke,[12] chloride by Bang's [13] method, and inorganic phosphate by the method of Bell and Doisy.[14]

The values for glucose differ, whereas those for the controls do not; observations of these differences, in both diabetics and non-diabetics, in four separate conditions are set out in Table I. These four conditions are (*a*) fasting at rest, (*b*) with a glucose meal, (*c*) under the influence of ether, (*d*) under the influence of insulin both fasting and with food. In the fasting state the results obtained from both diabetic and non-diabetic are given side by side in Table II.

TABLE II.—*Fasting at Rest.*

*G = Glycosuria.

From these results it would appear that in the non-diabetic fasting tends to produce identical values; therein confirming the work of Henriques and Ege,[3] and of Foster [6]; very short or very long periods after the meal, as in Nos. 3, 7, and 9, show a relatively higher arterial value. In the case of the diabetic it would appear that there is nearly always a fasting difference between arterial and venous levels. In severe untreated cases the difference is largest, and in some cases the venous value may be greater than the arterial.

Influence of Glucose.

The ingestion of carbohydrates causes a greater rise in the arterial value, as shown in Fig. 1. Fig. 2 shows the effect of carbohydrate ingestion two hours after a meal, when the arterial and venous values have not yet resumed their normal fasting relationship; it will be noted that the rise in neither is so great as in Fig. 3.

Exhibition of glucose to diabetics under therapeutic control produced the same type of difference as with normals—i.e., arterial values were higher than venous. We have not considered experiments on diabetics not under control to be entirely justifiable, but we imagine that the arterial-venous relationship would be similar to that obtained under the influence of ether anæsthesia in the diabetic (vide Fig. 4).

Influence of Ether.

The anæsthetic administration of ether to normal subjects also causes a hyperglycæmic effect, comparable with that which follows the exhibition of glucose and adrenalin. Arterial values are also again higher than venous.

Non-diabetic.

Subject.	Duration.	Arterial.	Venous.
(1) A. B.	15 min., ether	110 mg.	100 mg.
(2) J. C.	40 min., ether	171 mg.	150 mg.

Arterial and venous values were studied in a diabetic of moderate severity and under control, on whom a major operation was necessary; he entered the theatre with a venous concentration of 99 mg. glucose and a CO_2 combining power of 57 vols. per cent.—he was under ether anæsthesia for 40 min.; during the first period the arterial concentration was higher than the venous, but later, as his uncontrolled diabetic condition manifested itself, the venous

* Units of insulin. † Glucose administered.

In fasting normals small doses of insulin have little effect on the glucose level and the arterial venous relationship. In diabetics, on the other hand, insulin not only reduces both arterial and venous values, but, when the venous value is higher than the arterial, a reversal occurs.

In the normal, insulin, given after the ingestion of glucose, exerts a specific depressing action on the value of blood-sugar; the typical glucose curve is cut short, and, as shown in Fig. 5, the difference already existing between arterial and venous values is still further increased by the relatively greater fall in venous concentration. We would draw attention to this result, as, apparently, a specific effect of insulin. Using anæsthetised animals, this effect was not obtained by McCormick and others.

In the diabetic, as in normals, a general reduction takes place; in the case of serial investigations, the apex of the curve is removed (Fig. 6). After the exhibition of insulin the venous value, if previously higher, always appears to fall below the arterial.

Conclusions.

From the results which we have recorded above it is clear that the diabetic differs from the non-diabetic in his behaviour towards circulating glucose. These differences are: (1) Fasting and without insulin—the arterial value differs quite widely from the venous. (2) With glucose and ether and without insulin—there is a greater increase in both arterial and venous values, and in the fasting state the venous value may rise higher than the arterial. (3) With insulin—either fasting or with food—the relationships between arterial and venous values tend to approach those of the non-diabetic.

The tissue which is here at fault appears to be muscle. In order to explain these observations, it must be assumed that diabetic muscle tissue cannot take up glucose, or cannot hold glucose, or is giving rise to glucose; all these abnormalities are removed in some measure by insulin. Upon what mechanism does this depend? There are several factors which tend to establish the diabetic type of metabolism. They may be summarised in their probable effect on arterial and venous glucose levels: (1) Tending to raise arterial content—glycogenolysis in liver; decreased power of glycogen formation. (2) Tending to lower arterial content—excretion of glucose by the kidney. (3) Tending to raise venous content—glycogenolysis in muscle; breakdown of tissue protein into its potential 54 per cent. content of carbohydrates; muscle saturated with glucose yielding up its excess; possible synthesis of glucose from fat.

All or some of these factors are responsible for the differences observed between arterial and venous blood in the diabetic; but when, under the influence of insulin, the diabetic tends to approach the non-diabetic type in such relationships, which of these factors ceases to operate? From our results, it is, we think, strongly suggested that insulin so influences the behaviour of the diabetic that he can take up glucose from arterial blood and, by holding it in his muscles, in some form exhibit those lower levels with an arterial superiority over venous content which is characteristic of the non-diabetic.

This may be attributed to several causes, such as diminution of glycosuria, sparing of endogenous protein, increased glycogen formation, or increased carbohydrate metabolism. Both the latter are known to occur; increased glycogen formation has been shown to take place in the liver of depancreatised dogs fed with carbohydrate and insulin by Banting and Best[16]; the respiratory quotient has been shown to rise in diabetics by Banting, Campbell, and Fletcher.[17] From this investigation we would submit that the behaviour of the diabetic and the characteristic alteration obtained with insulin turns upon the factor of glycogen formation, as foreshadowed by Langfeldt,[18] although we are aware that Dudley and Mariam[19] did not obtain increased glycogen formation in the muscles of normal animals in whom insulin convulsions had been produced.

A CASE OF

CALCIFICATION OF THE PLEURA

OF AN UNUSUAL TYPE.

By F. H. YOUNG, M.B. Camb., M.R.C.P. Lond.,
MEDICAL REGISTRAR, CHARING CROSS HOSPITAL.

Calcification of the pleura and lung stones have attracted the attention of physicians from the time of Aristotle and Galen, and reports of cases can be found in their records.[1]

Until the advent of radiography the reports were those of cases discovered post mortem or at operation, but since radiography has become general in lung conditions, a considerable number of cases of various types of calcification of the pleura have been reported.

A general review of the subject was published by Pritchard,[2] and his conclusion, based on reports from literature and eight cases reported by himself, was that the origin of the condition was usually not tuberculous. The analysis of his cases shows that of the eight, three followed pneumonia, two pleurisy (cause doubtful), one probably tuberculosis of the lung, one trauma, and for one no cause was discovered. This case showed merely an isolated calcified plaque. In no case were tubercle bacilli found in the sputum. Respiratory symptoms were complained of at the time of examination in all cases except the last, and it is into the same class as this that the case described here apparently falls :—

---

[1] Aristotle and Galen, quoted by Flozzl, F., Gazz. med. di Roma, 1912, xxxviii., 562.

[2] Pritchard: Arch. Int. Med., 1923, xxxii., 279.

A. H., female, aged 54, was seen on account of pains in the legs and hips running downwards to the calves, worse on movement and relieved by rest. Six months previous to the date of examination she had been absolutely well, and denied any history of respiratory symptoms or disease. When seen she had no cough, sputum, or loss of weight, but she was slightly dyspnœic on severe exertion. There was no family history of tuberculosis. This history was confirmed by relatives. On examination she had signs of slight hypothyroidism. T., 97·4° F.; P., 80; R., 20. No enlargement of glands. Some evidence of osteo-arthritis of the hip-joints and some tenderness over both great sciatic nerves; C.N.S. otherwise normal. No abnormality detected in abdomen or in the urine. Pulses equal. Artery slightly thickened; B.P., 160/110. Chest well covered; antero-posterior diameter increased; movement poor, especially at the left base. Shrinkage of the bony cage on the left side. Heart not enlarged or displaced; sounds normal, but distant. Lungs—Left: note markedly impaired over the whole lung, especially in front, and in the axilla, except at the extreme apex and base. Vocal fremitus and resonance diminished in the left axilla, normal elsewhere; breath sounds diminished throughout and bronchial in character from the third rib in front downwards, and broncho-vesicular over the whole of the back; coarse râles, increased by coughing, throughout the lung. Right: normal, except breath sounds somewhat exaggerated and expiration prolonged. The radiograms reproduced here show a dense shadow outlining the left lung, and also the heart, in a lesser degree. There is some collapse of the lung at the extreme apex and also at the base.

Radiograms of a Case of Calcification of the Pleura.

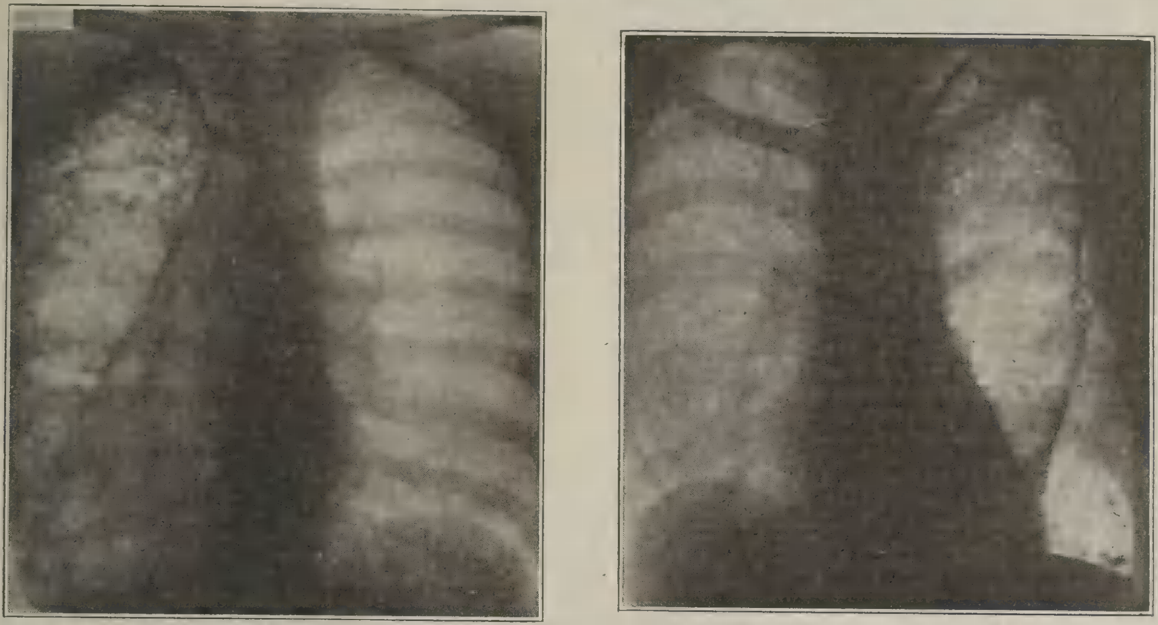

Plate in front.

Plate behind.

The points of interest about the case are: (1) the extent and the diffuseness of the calcification; (2) the absence of any respiratory symptoms at the time of examination; (3) the absence of any history of respiratory disease.

I am greatly indebted to Mr. G. Loughborough for the radiograms.

CULTIVATION OF THE SPIRILLUM OF RAT-BITE FEVER.

By TH. JOEKES, M.B. LEIDEN, M.R.C.S. ENG.,
LATE SENIOR DEMONSTRATOR IN PATHOLOGY, ST. BARTHOLOMEW'S HOSPITAL; CONSULTING PATHOLOGIST TO CHILDREN'S CLINIC, MARYLEBONE, N.W.

SINCE the discovery of the spirillum of rat-bite fever by Futaki, Takaki, Taniguchi, and Osumi [1] in 1915, numerous attempts have been made to cultivate this organism. Futaki and his co-workers claimed to have been successful with Shmamine's [2] medium, the cultures showing the organisms in great variety of shape and size from 1·2 up to 19 μ in length; they were, however, unable to grow them in subculture. These culture experiments have been repeated by many other workers as well as by myself. Using this medium at different pH concentrations, and incubating them at different temperatures, one nearly always obtains the "spirochæte" described by Futaki, but there is little doubt that one is dealing with "artificial spirochætes" as described by many workers. In 1922 Sangiorgi [3] records successful cultivations, but as no description of his medium has been given, and as repeated inquiries of the author have as yet elicited no reply, I have not been able to repeat his experiments.

During the course of my investigations with regard to the presence of the *Spirillum morsus muris* in the wild rats of London, over 25 per cent. of the rats were found to be infected. With a view to establishing whether all the strains found were identical, or whether they could be grouped in different types, cultures were made in the original Noguchi's medium and its numerous modifications, in most of the media used for the cultivation of the spirochæta icterohæmorrhagica as well as in the more commonly used media, under varying conditions as to reaction, temperature, and aerobiosis. All the cultures gave negative results.

In 1923 Vervoort,[4] in Sumatra, examined 258 patients with febrile attacks of unknown origin, and, using a medium composed of 1 g. peptone and 3 c.cm. normal phosphoric acid dissolved in 900 c.cm. distilled water, he succeeded in growing spirochætes in 25 per cent. of the cases. Extensive experiments with the medium again proved unsuccessful until, in analogy with Boeck and Drbohlaw's [5] method of cultivating amœbæ, media were tried consisting of Vervoort's medium poured on the top of a solid medium. At last, on trying a medium composed of an ordinary inspissated horse-serum-slope (as commonly used for the cultivation of the Klebs-Löffler bacillus) covered by 10 c.cm. of Vervoort's medium with a pH of 7·2 inoculated with blood of an infected guinea-pig, I obtained positive results. The cultures were positive after 24 hours' incubation at 37° C. aerobically. Incubation at lower temperature or under anaerobic conditions gave less satisfactory results. Of six primary cultures made from the blood of six different guinea-pigs three were successful, and have now been carried on until the thirty-fourth subculture.

The reaction found to be most suitable for the growth of these spirilla is pH 7·2 to 7·6. In this connexion it should be remembered that the serum-slope acts as a potent "regulator" or "buffer." It was found that the reaction of Vervoort's fluid, which is originally 6·6, had altered to pH 7 to 7·2, after having been warmed for 15 minutes to 37° C. in contact with the serum-slope. From this it is evident that the reaction of the Vervoort's medium should not be readjusted to pH 7·2 before adding it to the serum-slope, as if this were done it would become too alkaline on incubation. In some of the cultures the spirilla were still found alive and actively motile after three weeks, and it seemed to make little difference whether they were kept at room temperature or at 37° C. Once the primary cultures were obtained it was just as easy to make subcultures in 1 per cent. glucose broth—preferably with the addition of some defibrinated rabbit's blood—as in the original medium. In both the primary cultures, as well as in the subsequent subcultures, mainly short forms were found after 24 hours' incubation, and only comparatively few long forms, whereas after further incubation the longer forms became predominant. So far I have not succeeded in infecting mice with the cultures, neither have I been able to obtain cultures from infected mice, but only from guinea-pigs.

A few interesting facts have been observed with regard to these cultures—viz., all the cultures, although made under the most strictly aseptic conditions, showed a motile coliform bacillus as well as the spirilla. Experiments are still being carried out to determine whether this is a matter of obligatory symbiosis, as in the case of Kermorgant's [6] spirochæte of mumps, or whether the bacilli are simply a chance contamination.

With a view to separating the spirilla from these bacilli, cultures were filtered through Chamberland's L.2 filters. Although actively motile spirilla could be observed in this filtrate, but never any bacilli, subsequent subcultures from the filtrate were still found to contain the bacilli. These filtration experiments are being repeated with L.3 filters, and it will be interesting to compare the results with those of Salimbeni, Kermorgant, and Garcin.[7] These authors, working with mice infected with rat-bite fever, failed to find spirilla in the spleen, but a filtrate through L.3 of an emulsion of the spleen was found to be highly infective for mice. As a matter of fact, they found that mice inoculated with such a filtered emulsion became as quickly and as strongly infected as those which had been inoculated with strongly infected blood. Another interesting point of minor importance is the discovery that the presence of yeast in the cultures apparently killed the spirilla within 24 hours.

A further and more detailed report of the work done is to be published shortly. This work has been carried out partly at the Wellcome Bureau for Scientific Research, under a grant from the Medical Research Council, and partly at the National Institute for Medical Research at Mount Vernon. I should like to record my thanks to Dr. Andrew Balfour and Dr. C. M. Wenyon—past and present directors of the former Institute—and to Capt. S. R. Douglas and Mr. C. Dobell, of the latter, for all the kindly interest they have taken in the work and their many valuable suggestions. Last, but not least, I want to thank Dr. P. O. Ellison for his untiring assistance and collaboration throughout.

A CASE OF PSORIASIS.

ISOLATION OF MONILIA FROM THE SKIN SCALES, MOUTH, AND SPUTUM.

BY GERALD G. SANDERS, M.B., CH.B. EDIN.

THIS case of chronic skin disease, diagnosed in London and in India as psoriasis, is of interest on account of the isolation from the skin lesions, mouth, and sputum of a monilia, a member of a group found in thrush and allied infections and believed to be ætiological factors in disease in man.

Clinical Record.

Up to five years ago the patient, a married woman aged 36, was in good health. Her mother died with cancer in the stomach and secondary nodules in the liver. When travelling in India in 1920 the patient's foot was injured by accidental contact with the heel of a boot worn by another person. The skin on the dorsum was cut and she lost some blood. The cut did not heal, and in a day or two the skin around became discoloured, and a lesion similar to that shown at Fig. 1 (B) formed there. This lesion did not yield to treatment. Six weeks later she was alarmed to find on the external surface of both legs, around the knee-joint, similar lesions which became confluent; the disease then spread until the surface of both legs was partially covered. These lesions spread to various parts of the body, starting as small patches which rapidly became confluent. The skin condition has been described by more than one authority whom she has seen since 1920 as "typical of psoriasis," and in 1924 was again diagnosed as such. I saw the patient first on June 4th, 1925.

Condition on Examination.—On the skin on the lateral surfaces of both knee-joints large scaly lesions were seen; these were found also on the skin around the left hip-joint, on the back, on the left elbow, and also, to a lesser degree, on the face and scalp. In the sublingual region of the mouth an extensive white film seemed to cover the mucous membrane, and this film was seen also around an ulcer on the left margin of the tongue, an ulcer which had been present for a year and a half and which the patient associated with the friction of a dental plate. It was from one of my swabs from this ulcer that moniliæ were cultured; moniliæ were also found in the sputum, but they were not found in a special swab I took from the pharyngeal region. In the perineal region a number of short papillomatous tumours were seen, grouped together on quite a small area of the skin.

Organisms Described.—1. From scales of the skin lesion without culture; smear preparation Gram stain: (*a*) many Gram-negative coccidia; (*b*) streptococci and staphylococci.

2. From scales of skin lesion after culture in bouillon, 48 hours at 37° C.: (*a*) moniliæ and Gram-negative coccidia; (*b*) branching mycelial threads; (*c*) streptococci and staphylococci.

3. From sputum; smear preparation Gram stain: (*a*) Gram-positive cocci; (*b*) Gram-positive short chain streptococci; (*c*) Gram-positive diphtheroid bacilli; (*d*) Gram-negative cocci.

4. From sputum after culture at 37° C. for 48 hours: (*a*) a few colonies of monilia; (*b*) *Streptococcus brevis*; (*c*) *Staphylococcus aureus*.

5. From region of ulcer in left side of tongue, special swab, smear preparation Gram stain: (*a*) monilia; (*b*) streptococci.

6. From mucous membrane sublingual region; special swab, smear preparation Gram stain: (*a*) monilia; (*b*) streptococci.

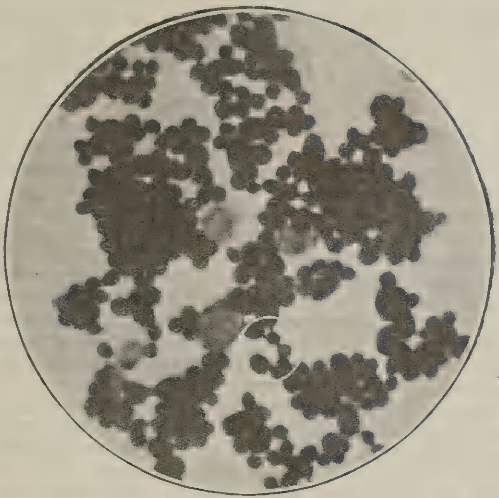
7. From nasopharynx; special swab: (*a*) cultures sterile.

8. From urine and fæces no moniliæ were obtained; but many Gram-negative bacilli and Gram-positive streptococci.

The following are fermentation tests of moniliæ isolated on agar slope:—(1) Glucose: acid and gas. (2) Lævulose: acid and gas. (2) Maltose: acid and gas. (4) Saccharose: acid and gas. (5) Lactose: acid, mostly gas. (6) Raffinose: alkaline, no gas. (7) Adonite: slightly alkaline, gas. (8) Sorbite: strong alkaline. (9) Galactose: acid. (10) Mannite: acid, slow gas. (11) Dulcite: no reaction. (12) Insulin: no reaction. (13) Litmus milk: alkaline. (14) Neutral red: gas.

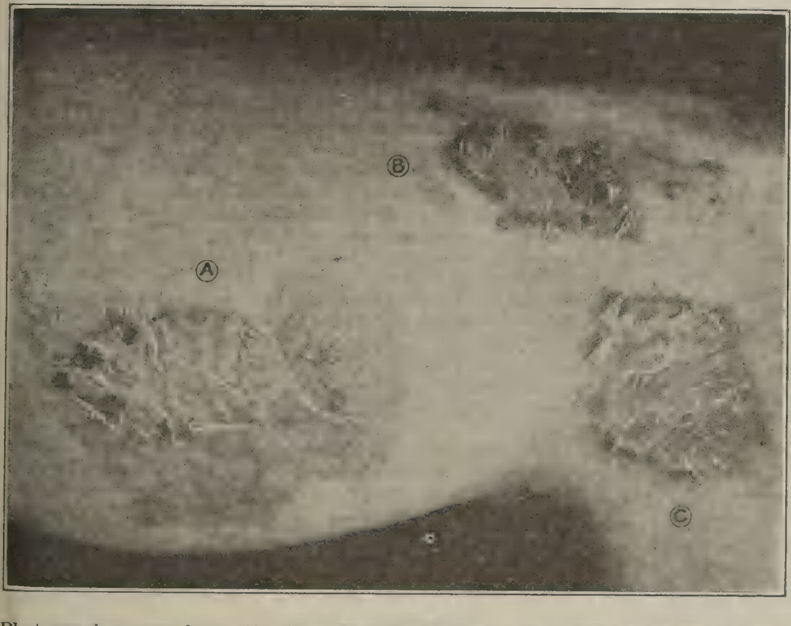
Moniliæ.—Macroscopic characteristics: on glucose agar the colonies of moniliæ appear as white, creamy colonies, about a quarter of an inch in diameter in many cases. Microscopic characteristics: the moniliæ appear as large Gram-positive cells (Fig. 2) frequently producing buds and mycelial threads. In this and other microphotographs from this film a sort of fine reticulum forms a bridge connecting each monilia. The word monilia means "necklace," the reticulum suggesting the "string" of the necklace. In Fig. 2 attention may be drawn to cells which take the Gram stain only in part of their substance; the remainder of their substance is stained with the counterstain. The Gram-negative coccidia are not included in this photograph, though they are cleary visible at this power in many of the films.

FIG. 2.



Photograph (× 1000) of moniliæ stained by Gram method. Four cells have only partly taken up the Gram stain. Within the circle can be seen the fine reticulum connecting the moniliæ.

FIG. 1.



Photograph on panchromatic plate of lesions on the outer surface of the left leg in the region of the knee. The patch B is untreated; that at C has been treated with copper sulphate lotion (1 to 100), and that at A with tinct. iodi (10 per cent. in 90 per cent. alcohol); in both cases two days before the photograph was taken.

Summary.

These analyses and the information they give have an important bearing on treatment. They show that in the skin lesions and the mouth the streptococcus and the monilia are closely associated; the streptococcus is shown to be the more widely distributed organism as it was found in alimentary tract and urine, in the latter situation with *Bacillus coli.* The hæmoglobin was shown to be 60 per cent., but full count of the blood cells showed that otherwise there was no change from the normal. The patient appeared toxic, and had painful rheumatic symptoms in the left shoulder region as well as pain in the suprapubic region. These symptoms disappeared later, at which time the urine was shown to be sterile after 20 days treatment with urotropine. Antistreptococcic serum (Parke, Davis and Co.), polyvalent, was given subcutaneously to the extent of 30 c.cm. in all; the first dose was given in divided quantity, 9 c.cm. two hours after a preliminary injection of 1 c.cm. The right ankle became tender during the following few days, and there was a reaction throughout most of the skin surface; much redness and a sort of nettle-rash and itching. The serum was undoubtedly beneficial and later, after six detoxicated vaccines, made from the streptococci isolated from the skin lesions, all the painful back symptoms were removed. I propose to give another six of these vaccines. It is not possible here to go into the condition of the teeth, which were probably responsible for much of the streptococcus infection. I suggested ultra-violet light treatment for the skin condition and hope this may be applied to the mucous membrane of the mouth.

The patient is now having ultra-violet light treatment at one of the London hospitals.

Acknowledgments are due to the Associated Clinical and Analytical Laboratories, Ltd., London, for laboratory assistance. I have availed myself of the opportunity to submit these organisms to the Curator, National Collection of Type Cultures, Lister Institute of Preventive Medicine, Chelsea, London, S.W., so that they may be preserved. Further research by fermentation and other experiments, and animal inoculation tests is very desirable.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

A meeting of this Section was held on Dec. 3rd, Mr. T. G. Stevens, the President, occupying the chair.

Exhibition of Specimens.

Dr. Everard Williams sent descriptions and slides of two specimens. The first was that of a Fallopian tube containing a loose fragment of menstruating endometrium associated with endometrioma of the ovaries. The patient had had for some time dysmenorrhœa, and this had been getting worse. The specimen consisted of both ovaries and tubes, and the uterus was covered with numerous dense adhesions, while there were cysts containing tarry material, these cysts having ruptured during the removal. Adhesions had bound the ovaries to the back of the broad ligaments, so that removal of the Fallopian tubes became necessary. These tubes, however, were seen to be free, and were normal in appearance. Both ovaries contained abundant endometrium in a non-menstruating phase. The right ovary was exhibited on the screen, showing on one side endometrioma, on the other side ovarian tissue containing an early developing Graafian follicle. A similar condition was present in the left ovary. In the right tube, in the region of the fimbriated extremity, were two fragments of tissue lying free and separate from the tubal mucosa. Those fragments proved to consist of endometrial tissue not in a menstrual phase of the cycle. The specimen, it was contended, confirmed the view of J. A. Sampson, of New York, as to the causation of this condition.

The President said he regarded this specimen as the missing link in the pathology of endometrioma. Many observers had been trying for some time to find endometrium in the Fallopian tube, and now it was forthcoming. He had always believed that Sampson's view would prove the correct one.

Dr. Cuthbert Lockyer said this was the most convincing proof which had been seen up to the present. Several observers had found fragments of endometrium in the menstrual blood in the pouch of Douglas, but this to-night was the most convincing evidence of the transference along the tube of necrobiotic endometrium. But in accepting the implantation theory as one explanation of endometrioma, one must be careful not to push it too far. What the profession was awaiting was information as to a common genesis for all these and similar conditions.

Dr. W. W. King said he thought such a fragment would have difficulty in getting through the uterine end of the tube. He did not see why it should not have grown there. He found acceptance of Sampson's view difficult, as for damaged tissue to implant itself on undamaged tissue was unique in pathology.

The second specimen shown by Dr. Williams was a uterus showing multiple polypi of the cervix. The uterus was removed by vaginal hysterectomy. Examination showed nothing abnormal except that the cervix felt rough and irregular, and there was no bleeding on examination. A more complete examination under an anæsthetic showed that the cervical condition extended far up the canal, and that the roughness previously felt was due to large numbers of polypi. The specimen showed an unusual condition of the cervix; the endometrium was replaced by a diffuse growth of polypi, and the condition ceased abruptly at the level of the internal ostium. There was no evidence of chronic inflammation, therefore it was thought the condition was new growth.

Gliosarcoma in a Still-born Fœtus.—Ruptured Acute Pyosalpinx.

Mr. D. J. Malan gave a short communication on a case of gliosarcoma in a full-time still-born fœtus. There was nothing abnormal in the placenta nor in the amount of liquor amnii. No abnormality in the fœtal head was suspected, but when the fœtal head was opened it showed bilateral internal hydrocephalus. There was some tearing of the tentorium cerebri, but no signs of hæmorrhage. In the cerebral hemisphere was found a round lump, and enclosing it was a very much flattened cerebral cortex, ½ cm. thick, covered by smooth lepto-meninges. Another, smaller, gliosarcoma was found in the other side of the cerebrum. The doctor in this case had been blamed for causing the state of affairs by putting on forceps prematurely and damaging the baby. The real cause of the baby's death was the tumour. He advocated more routine examination of fœtuses, when it would probably be found that such occurrences were not so rare as they were supposed to be. He also gave a description of a ruptured acute pyosalpinx which occurred in the third month of pregnancy, the patient being 37 years of age. There was abdominal pain, great nausea, and some vomiting, with a blood-stained, offensive vaginal discharge. The temperature was 101° F., the pulse 96, tongue moist and furred, and the abdomen very tender. The uterus was enlarged to the size of a two-months' pregnancy. On doing a laparotomy free pus was found in the peritoneal cavity. The left Fallopian tube had a perforation 4 cm. wide, and pus was oozing from this rent.—Several members discussed the communications.

Puerperal Sepsis.

Papers on puerperal infection were read by Dr. H. J. Phillips (Monsall Hospital, Manchester) and Dr. L. Colebrook (London).

Dr. H. J. Phillips spoke on Rational Treatment of Puerperal Infection, and said his intention was to deal mainly with the results obtained from the treatment of a series of cases along certain constant lines. The work was done at the Monsall Hospital, which was Manchester's infectious hospital. Here 22 beds were set apart for puerperal cases, and the admissions during a year varied between 90 and 120. Every encouragement was given to send cases as soon as possible, and none was refused, yet still many were too advanced and serious when received. In his experience of puerperal infection he had been much impressed by the great amount of extra-uterine injuries suffered by these patients, and the gravely septic nature of the region when patients were brought. He was not now speaking of tearing of the perineum. On exposing the vagina, remains of a lacerated cervix covered with foul sloughs, teeming with micro-organisms, were frequently found. The uterus of such a patient could easily become infected, and if the local defences failed, the infective process could become widespread. Though the acid secretions of the vagina might keep micro-organisms inert, in the alkaline lochia and the body tissues they might rapidly show pathogenic properties. Merely to drain the cavity or attack the endometrium was not likely to produce good results; therefore he had hoped for some means of helping the uterine wall to drain itself by promoting a flow of lymph through it into the cavity. Some time ago he had the opportunity of seeing glycerine used in the uterus for this purpose, and it seemed to him it might solve the problem, as it was a powerful tissue dehydrant, and its viscidity enabled it to remain for a long time in contact with the tissues, while at the same time there was no danger to the patient. The mixture he used was a 10 per cent. solution of tincture of iodine in glycerine, the iodine promoting the flow of lymph into the cavity of the uterus. Most of the patients were drained in this way once daily, the more severe cases twice a day. In the first 100 cases the average number of applications was seven, the treatment being continued until all active inflammation had subsided. In this method the local condition was well exposed and could be thoroughly cleaned, and there had been a rapid healing of the lesions. The chief source of trouble was the paravaginal abscess associated with a badly torn vagina. Pus was found in the uterus in half the severe cases, usually only in small quantity, though in one case it amounted to 6 drachms. Often the doctor had assumed from the presence of a profuse purulent vaginal discharge that the uterus was draining well, the fact being that none was coming from it, the suppuration being high up in the vagina. The introduction of the iodine and glycerine tended to produce uterine contractions. In 130 cases in which he had employed lymph drainage (glycerine drainage) he had never explored the uterus, except for primary hæmorrhage; fragments of membrane, placenta, or decidua had come away in the manner spoken of.

Comparison of Results.

Dr. Phillips, for purposes of comparison, gave two series of cases and the results achieved. The first consisted of 87 cases which were treated by lymph drainage, and the second of 110 cases which immediately preceded the first named. In both the cases were of the same type and drawn from the same district. Before lymph drainage was done at the institution the treatment of these cases had been carried out on three main lines. The milder cases were dealt with expectantly—i.e., with vaginal douching, Fowler's solution, quinine, &c.; the more severe with anti-streptococcal serum or curetting. Of the 110 cases, 29 per cent. developed complications, 11 developing pus and needing operation; while of the 87 cases treated by lymph drainage, only 14 per cent. developed complications and only one developed pus. Dealing next with the mortality in the two series, that in the first 100 cases was 13 per cent., the lowest in the institution for many years; and all died of some condition which was already established when the patients entered the hospital. Also, since this method was inaugurated the average stay in the hospital had been greatly reduced, from 41·5 days to 26·2 days.

Acute Blood Infections: Laboratory Investigations.

Acting on Dr. Colebrook's suggestion, he had adopted two lines of treatment in cases with acute blood infections—namely, the intravenous injection of arsenical drugs, and the transfusion of immunised blood to help the patient's own defensive mechanism. The drug chosen was novarsenobillon. Disappointing results followed the use of small doses of arsenical preparation, large ones were followed by clinical improvement. He exhibited lists of cases giving many details.

Dr. L. **COLEBROOK** spoke of laboratory investigations which he had been carrying out on the same subject. He said that in considering what was the chief microbic agent of puerperal sepsis it was not necessary to go further than the hæmolytic streptococcus, which was probably the cause of 90 per cent. of the troubles of septicæmic cases and localised infections. There was no reason for supposing that puerperal sepsis was due to a special streptococcus. As to how the streptococcus usually gained entrance into the genital tract, it was generally taught that it was not normally present in the vagina, nor in the rectum, and he thought infection from both those sources must be rare. The problem here did not differ from that of surgical wounds generally. Ordinary non-hæmolytic streptococci were more easily killed by leucocytes than were the hæmolytic form. Was there any evidence that a woman's resistance to the streptococcus was lowered during the process of pregnancy and labour? There were now available means of knowing how efficient a person's blood was in killing streptococci, and it was found that there was no general tendency for the killing power of a woman's blood to be lowered during pregnancy and labour. He believed that blood invasions from the genital tract were more common than they were generally supposed to be. Blood in the capillaries had great power of killing off streptococci, and if a few of these organisms got through in the first few days of labour, if the woman's blood was normal, there was but little chance of those microbes surviving in the capillaries. But the woman's blood might not be normal, and in septicæmia the killing power of the blood was greatly reduced; it might be only 40 per cent. of the normal. The real reason was that in septicæmia the leucocytes were not normal ones; probably the microbes produced a toxin which was disabling to them. Then the microbes getting through would be able to survive. When a blood culture was done on a doubtful case of septicæmia, the bacteriologist should be asked to state how many microbes he found to the cubic centimetre; that gave important prognostic information. He had only seen one woman recover who had more than 100 streptococci per c.cm. in her blood.

With regard to local treatment, this, it would be agreed, was not at the moment all that could be desired. Two lessons learned in the war experiences were: that wounds infected with hæmolytic streptococci and containing damaged tissue and blood clot could not safely be left to themselves. Hæmolytic streptococci, as Sir Almroth Wright showed, could grow comfortably in damaged bloodless tissues and in blood clot. As the streptococci grew, the containing fluid lost all its bactericidal power, and at the same time the leucocytes were held back. Something of that kind must occur in the case of an infected wound of the genital tract. The worst cases of puerperal fever were those in which the lochia were suppressed and those in which instruments had been used and caused bruising of the tissues. And the war's second great lesson in this regard was the efficacy of fluid drainage, which Dr. Phillips had demonstrated in his series of cases.

Concerning general treatment Dr. Colebrook said that in septicæmia there were often millions of streptococci in the circulation, and the defensive mechanism of the patient was largely out of action. It was necessary either to have an agent which would kill off many streptococci and so give the leucocytes a chance to recover, or there must be an agent which would neutralise the toxins which were damaging and inhibiting the leucocytes. Antistreptococcic serum appeared to have no strong place; to do any effective killing of the bacilli, a pint of it would have to be given. With regard to drugs, the most hopeful of those he had worked with was neosalvarsan, and the killing power of that was pronounced in a strength of 1 in 100,000, reducing 526 streptococci per c.cm. to 3 in five hours. Concerning transfusion, one could not hope to save a patient by this alone. Reasons for this probably were that by defibrinating blood one deprived it of about 30 per cent. of its corpuscles and mixed it when transfusing with nine times the quantity of the patient's own blood. Still, he thought it was right to go on working at drugs and transfusions.

Prof. **LOUISE MCILROY** said the results she had had from carrying out Dr. R. Hobbs's treatment (injection of glycerine) had been extraordinarily good, drainage having been done for seven days. Most of the cases of puerperal sepsis were due to laceration. Recently she had been raising the patient's immunity by giving antistreptococcus serum and quinine before clearing out the uterus, and the results had been such that she intended to continue the practice. Results from blood transfusion seemed to last only four or five days.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.

A MEETING of this Society was held at 11, Chandos-street, W., on Nov. 27th, Dr. WILFRID S. FOX, the President, occupying the chair.

Medico-legal Problems in Relation to Venereal Disease.

Dr. F. G. CROOKSHANK read a paper on medico-legal problems in relation to venereal disease, which, he said, touched on the provinces of ethics, politics, sociology, religion, and jurisprudence, and could hardly be appreciated without some acquaintance with history and with human nature. The crux of the question was that, however loudly some might say that venereal diseases were not different from other diseases, human nature would never permit these diseases to be dealt with by the *ordinary* routine of notification and sanitary administration. Venereal disease was fundamentally one of the consequences of breaking the social-sexual code, and the occurrence of venereal disease in a population always seemed to be associated with the breaking of a social code, no matter what that code had been. He thought it might be taken as axiomatic that however the social or moral code might change, and whatever degree of promiscuity or liberality in sexual matters might be allowed—and, of course, the sexual and moral code had changed in an extraordinary way during the last ten years—yet the imputation against a person that he had venereal disease would always be actionable. To say of anyone that he or she was unchaste might at one time have induced social avoidance, though it by no means necessarily followed that it would always do so, but the presence of venereal disease would continue to make a person shunned by even the most degraded. He did not see how the lawyers could draft any Bill which, merely by making the communication of that disease to another person an offence, would be effective in the prevention of venereal disease unless doctors could definitely say, in more than a few cases, that the suspected person *must* have known himself or herself to be in an infective condition. If it was desired to constitute a new kind of offence it would have to be proved that there was guilty intention, and that the person knew what he was about. This meant that it would be necessary to prove warning. Could warning be proved unless communication had been made to some third person?

Mr. EWART WORT, Barrister-at-Law, pointed out that while in respect to some sexual offences the law usually required corroboration, a conviction in such a case as Dr. Crookshank had instanced would depend upon whether the doctor was to be believed when he said he had given warning, or the accused person was to be believed when he denied it, and from his own experience at the Bar the doctor's evidence would be accepted.

Dr. CROOKSHANK said that, at any rate, it would be impossible to induce lawyers to recognise as an offence an act of this nature unless it could be shown that the person who committed the act really understood his state and had been warned in respect of his infectivity. Germany and Sweden appeared to have adopted legislation in respect to the communication of venereal disease, and their experience must be valuable. While, no doubt, a medical examination before marriage would be an ideal arrangement, he could not help feeling that one could not go safely beyond the requirement of a statement on oath by the parties made at the very last moment. He recalled a case within his own experience of a man who only on his very wedding day discovered that he was suffering from venereal disease, the last illicit connexion having dated from three months previously. The very fact that some such declaration was required at the last moment might go some way to induce a feeling of responsibility. It seemed necessary, however, to fall back upon the continuation of the present state of affairs, even if there was occasional occurrence of the position so often alleged to be frequent, wherein Dr. A was aware that Mr. B had venereal disease and intended, in spite of all expostulation, to marry Miss C. In England a breach of professional confidence was not an offence in itself and so punishable, as was the case in some countries abroad. If a medical man broke professional confidence by saying that a certain person was syphilitic and so injured him, it was possible for that person to bring an action against him for slander or libel, but not for breach of professional confidence. The doctor (granted, of course, that he was sure of his ground) should, however, be prepared to take the consequences, which the speaker did not believe would be serious to himself under such circumstances, and to warn Miss C or her parents. In such difficult cases members of the profession should have the courage of their convictions. If they technically broke the law and uttered slander in order to prevent the marriage of a syphilitic to an innocent person he did not think that in the long run the law would punish them very severely, while there was nothing in the oath of Hippocrates to prevent any man conscientiously breaking professional confidence in such circumstances.

Mr. WORT dealt principally with the compulsion upon witnesses to give evidence in courts of law. There were certain exceptions to such compulsion. On the grounds of public policy, no husband or wife was compelled to make a statement which was the result of communication by the other. No person was compelled to give evidence in a court of law when the evidence would incriminate himself. And there was the third exception, the privilege which a member of the legal profession enjoyed in regard to communications made to him in the course of his professional activities. This last was an anomaly, but it was absolutely necessary by reason of the fact that without that privilege the administration of justice could not be carried on. It might be asked, why the distinction between the medical and the legal professions in this respect? But the point was that of all the information obtained by the medical man in the course of his profession, not one-thousandth part would ever be the subject-matter of litigation, while in regard to the communications made to a lawyer, every such communication carried the potentiality of litigation. This privilege of lawyers was not the privilege of a profession as such; it was the privilege attaching to a particular kind of communication. Dr. Crookshank had referred to the law in other countries. It was part of the penal code in France that any communication made by a doctor in breach of his professional oath was a criminal offence, but there was an exception—namely, when he was compelled to give evidence in a court of law. If further legislation was necessary in order to get to closer grips with the social problem put forward by Dr. Crookshank, it was for the medical profession above everybody else to educate the public up to the point of such legislation. Any legislation making it a penal offence to communicate this disease to an innocent person must take into account the state of knowledge of the person indicted. An analogous class of case in this respect was the receiving of stolen property, which was extraordinarily difficult to prove. The law had surmounted the difficulty by putting certain tests which the jury were instructed to apply to the particular case. One such test was whether the person had purchased the property at a very low price; if he had done so it might be justifiable to suppose that he knew it to have been stolen. Whether some similar tests could be applied to persons suffering from this disease was for the medical profession to state. In the case cited by Dr. Crookshank of Dr. A, Mr. B, and Miss C, the only possible action would be an action for slander, and to such an action justification was a complete defence. But there would be a further defence in the shape of what lawyers called qualified privilege. The difficulty with medical evidence, however, was that occasionally Dr. A went into the box and said one thing, and Dr. Z another.

Discussion.

In the course of the discussion Colonel L. W. **Harrison** spoke of the need for circumspection in relation to venereal diseases clinics. It would have a most disastrous effect if the public were deterred from coming freely to get treatment by the fear that there might under certain circumstances be a disclosure of their condition.—Dr. D. N. **Nabarro** put the case for legislation to compel parents to have their children who were congenital syphilitics treated.—Mr. **Wort** said that there was no specific legislation in this matter, but, of course, a parent could be prosecuted where it was proved by a medical man that a child was being wilfully neglected through not receiving treatment.

Exhibition of Clinical Cases.

Dr. H. McC. **Hanschell** showed two clinical cases, one a case of ulcerating granuloma in a Chinaman, which he had already shown eight months previously before the Society; and the other a case of congenital syphilis in a boy, which, in addition to the characteristic facies, showed necrosis of the maxilla.

Dr. P. H. **Manson-Bahr**, in alluding to the first of these cases, said that it was a very interesting condition and occurred in definite geographical areas in the tropics, being very common in New Guinea. It was also found in Chinese treaty ports, in South Africa, and in the West Indies. Dr. Hanschell's case was the sixth consecutive one he had treated during the last four years. There was no doubt whatever that antimony tartrate was specific for this disease, among others. The substance must be given by the intravenous route, and must be persisted in for months. It should be given in 1 or 2 per cent. solution, commencing with ½ gr. dissolved in 5 c.cm. of distilled water, and gradually increasing to the maximum tolerated dose. The maximum dose one could give was 5 gr. a week. Intolerance was usually shown by acute muscular pain. Local measures were of the utmost importance. Ulcerating granuloma had the peculiarity of spreading in one direction while retreating in another. It might burrow underneath the pubic region and extend in the scrotum. More recently he had used antimony tartrate in paraffin ointment; this was spread on the ulcerating surface, and left on for about two and a half hours, care being taken that it did not impinge upon the healthy surrounding skin. Antimony tartrate appeared to cause a considerable degree of local reaction and sloughing. In these cases one should never give up hope. A point to emphasise was the inadvisability of surgery. In one case in which the healing by medical treatment was successfully accomplished after three and a half years, surgery was practised at one point, and immediately expansion took place at the edges of the wound.

Dr. **Nabarro** referred to the second case shown by Dr. Hanschell. In all the cases he had had under his care at Great Ormond-street, numbering over 500 now, he had only in one instance seen necrosis occur in the position shown in the case exhibited that evening. There was no doubt that the boy had had also some gummatous necrosis of the bones of the skull. In a case of this kind he would advise that the cerebrospinal fluid be examined, and if it proved to be positive, salvarsan serum should be given.

LIVERPOOL MEDICAL INSTITUTION.

At a meeting of this Institution on Nov. 26th Dr. **John Hay** and Dr. **Phœbe Ince** communicated a short paper dealing with the uses of

Diathermy in Cardiovascular Disease,

more particularly in patients with angina, major and minor, in cases of high blood pressure with various manifestations of distress, and in one case of intermittent claudication. Some of the patients had been kept under observation over a long period and the effects of the diathermy had been noted for the last two years. Weekly records had been kept of the variations in blood pressure, both systolic and diastolic, in the heart rate, and in the clinical findings, showing the response to treatment. In most instances there was definite improvement, in some cases dramatic improvement. Not only were the pressures reduced as the immediate result of treatment, but when the course of treatment terminated the improvement was maintained. In nearly every instance, whatever the variations in blood pressure, there was marked subjective improvement. The response to treatment was much more satisfactory in the males than in the females. In considering these results there appeared to be no doubt as to the benefit derived from this line of treatment.

Mr. R. E. **Kelly** read a paper on

Grafts and Grafting.

After a brief historical survey he considered the various methods of skin grafting. He said that the essential features in a successful Thiersch graft on a granulating area were as follows: 1. The area must have a flat instead of a heaped-up edge. This could be obtained by Beck's method of protecting the growing epithelial margin by strips of half-inch Z.O. eye strapping for a few days. By this means the exuberant granulations were flattened out and the marginal cranny of sepsis obliterated. Further, it saved the delicate new epithelial edge from being pulled off with the dressing. The last dressing should consist of 50 per cent. alcohol. 2. The granulating area must neither bleed nor weep. It should show neither sloughs nor bruises. 3. The operation should be done with absolute dryness. As Ochsner showed, there were disadvantages in moistening the razor with saline, glycerine, or antiseptics. No dressing was needed. Around the area a nest of gauze was placed and on top of this, but not touching the grafts, a piece of celluloid was fastened down with strapping. In immediate grafting Mr. Kelly spoke of the value of a stent or dental wax cast over the graft so as to apply even pressure and prevent the exudation of serum between the bed and the graft. He then spoke of the inlay grafts of Esser, Gillies, and Pickerill, and showed examples of eyelid grafting for ectropion and whole skin grafts for the deformity following lupus of the nose. Photographs of the tubed or jug-handle graft were shown illustrating the restoration of a lower lip lost by cancrum oris in infancy. Mr. Kelly spoke of Gallie's work on the tensor fasciæ femoris and its multifarious uses as a grafting material. He showed cases in which he had used it for uniting a fractured patella, for repairing an extensive post-operative hernia, and even repairing an inch gap in the extensor secundi internodii pollicis tendon. In the last case the result after a year was complete and strong movement of the terminal phalanx in complete contrast with a similar operation done for the flexor tendons of the palm. Despite primary union the palmar operations had failed. There appeared to be too much fibrosis and the grafts had stuck to the palmar fascia. Cartilage grafts for nasal deformities were next considered. They were extremely useful in accidental depressions, but were apt to be disappointing for cases of congenital syphilis. Finally, Mr. Kelly described his method of wedge-shaped bone grafts. He had used this for the fibula to prevent the slipping of the peroneal tendons and in the tibia to bridge a gap of an inch or so. The paper was illustrated by lantern slides and the result shown in a preliminary exhibition of patients.

Improvements at the Metropolitan Hospital.—With the approval and help of King Edward's Fund the Metropolitan Hospital in the Kingsland-road, which serves the poor and densely populated districts of Shoreditch, Haggerston, Hoxton, Hackney, Bethnal Green, and Stoke Newington, is about to make improvements which will cost £54,000, of which nearly one-half has still to be raised. The principal work is the erection of a home for the nurses, who at present are scattered over "a jumble of broken-down property," most inconveniently situated, with passages so dark that gas has to be kept burning continually, but there will also be two new accident wards.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, ST. ANDREWS.

At a meeting of the Institute on Nov. 24th Dr. Ivy Mackenzie gave an address on

Insulin in the Treatment of Toxic Delirium.

He explained that by toxic delirium he meant the condition recognised in psychiatric practice as "exhaustion psychosis," and sometimes referred to as toxic confusional insanity or amentia. The condition itself might be readily recognised by those who had an opportunity of seeing a large number of mental or nervous cases. It supervened on the basis of chronic nervous disorders of a hysterical or neurasthenic character; it sometimes occurred in the puerperium and also after the production of an artificial menopause. It began suddenly with excitement, sometimes of a violent character; the excitement passed into delirium, and if this stage were survived it was followed by a period of confusion which tended to clear up after a time. This form of illness he had seen only in women, and during the last year there were 18 cases among the 350 women who had passed under his notice in the mental observation wards in the Eastern District Hospital, Glasgow.

Hitherto he had treated such cases with chloral with some success. A year ago, following a discussion with Dr. J. H. Burn on the action of insulin and its relation to other internal secretions, he employed that drug in three cases. The beneficial effect was beyond doubt and compared favourably with its influence in diabetes mellitus. Treatment was begun with 5 units thrice daily, and this was gradually increased to 7, 10, 12, and sometimes to 15 units thrice daily. Chloral was employed, but mostly at night only. In some cases the patients appeared to be more susceptible to the poisoning action of chloral when insulin was given. One death occurred, and that in a woman who had also chronic renal disease and arterial degeneration; 14 had been discharged recovered, although some of these exhibited signs of what was probably their "nervous state" prior to the acute illness; three were convalescing; no patient suffering from this condition had been certified for asylum care since the treatment was initiated. Referring further to the clinical aspects of the cases, it was pointed out that fever was sometimes present, and that a leucocytosis of 10,000 to 20,000 was present in all except two. The blood-sugar curve was abnormal at some time in every case. It was frequently of the diabetic type, but occasionally there was an abnormally low curve, as, for example, in one case where the estimation was 0·05 per cent. on the fasting stomach, 0·09 per cent. at the height of the curve after 50 g. of glucose, 0·075 per cent. after an hour, and 0·06 per cent. after two hours. Notwithstanding the low estimate insulin was given, and after a week, when the patient had made considerable progress toward recovery, the curve had risen and showed the diabetic features with 0·135 per cent. on the fasting stomach, rising to 0·21, 0·25, 0·18, and 0·165 at half-hourly intervals. A striking feature of the metabolic abnormality was the presence in some cases of a blood-sugar content of 0·3 per cent. with no sugar in the urine, and no evidence of renal disease. The participation of the endocrine system in the upset of metabolic equilibrium which characterised the illness was probable. Reference was made to the experimental and clinical evidence of the relation of the ductless glands in diabetes, and in the case of toxic delirium it was pointed out that the abnormality of the ovarian system in all likelihood played a part. It was likely that the therapeutic use of insulin would be extended beyond the limits of diabetes mellitus, and that it would afford a means of approaching a solution of the problems not only of the ductless glands, but of a whole series of syndromes in which disordered metabolism played a part.

Reviews and Notices of Books.

Modern Medicine, Its Theory and Practice.

An original contribution by American and Foreign Authors. Edited by Sir William Osler, M.D., F.R.S. Third edition, thoroughly revised. Re-edited by Thomas McCrae, M.D., Professor of Medicine in the Jefferson Medical College, Philadelphia, assisted by Elmer H. Funk, M.D., Assistant Professor of Medicine, Jefferson Medical College, Philadelphia. Vol. I.: Bacterial Diseases; Non-bacterial Fungus Infections; the Mycoses. London: Henry Kimpton. 1925. Pp. 845. £12 12*s.* per set of six volumes.

In his preface to the first volume of the new edition of this monumental system of medicine Dr. McCrae states that at about the time of the onset of Sir William Osler's last illness (some six years ago) correspondence was taking place as to the possibility of a third edition. It was a gratification to him to feel that this was being called for. Dr. McCrae adds some interesting personal notes as to the origin of the work which was to bring such widespread fame to its editor. At the first consideration of the possibility of his bringing out a system of medicine, Sir William Osler felt apprehensive that it might be too great an additional burden in his busy life, but finally consented to undertake it. With the work once started he became much interested and the success of the first and second editions pleased him greatly. His conception of the right article for a system was a discussion of a subject at a length between the brevity in a text-book and the extensive consideration possible in a monograph, with the needs of the general practitioner kept well in mind. For the most part he was able to inspire his contributors with his own ideals, and the result was a well-balanced work which merited the popularity it received.

In the 12 years that have elapsed since the first volume of the second edition appeared many changes have occurred in our knowledge of disease, and new diseases, such as botulism and epidemic encephalitis, have come into prominence. The discovery of the ætiological agent or further study as to the cause has altered many points in the control and treatment of some diseases, such as scarlet fever and bronchial asthma. A new therapeutic aid has come into prominence, altering the whole aspect of the treatment of diabetes mellitus. In the present edition the discussion of the pathology of tuberculosis by Dr. A. K. Krause is a departure from the traditional method. Dr. Du Bois gives a clear and comprehensive concept of the modern problems in metabolism. As to the subject-matter of this first volume, it has been to some extent rearranged. With the exception of the short section on fungus infections, the whole book is devoted to bacterial diseases. Scarlet fever has been placed among these, but the other exanthemata and fevers of doubtful causation, including rheumatic fever, are no longer included. The articles on typhoid fever, lobar pneumonia, and tuberculosis occupy more than half of the volume; the first two of these retain their old form, but have undergone revision and enlargement. As already stated, the section dealing with the pathology of tuberculosis has been rewritten, and a large amount of new material has been incorporated in the sections on other aspects of that disease. The shorter articles contained in the second half of the book have received numerous additions embodying the advances of the last 12 years.

Dr. McCrae has rendered great service to the medical profession in keeping up to date so valuable a work and in perpetuating the memory of its first editor. The essay on the Evolution of Internal Medicine, written by Osler in 1907 as an introductory chapter to the first edition, and omitted from the second, has been restored, and may claim a high place as a classic in the literature of the history of medicine.

THE MODERN PRACTICE OF TOOTH EXTRACTION.

By LESTER RICHARD CAHN, D.D.S. New York: The Macmillan Company. 1924. Pp. 132.

THE fundamental principles of tooth extraction are based on the application of mechanics to the anatomy of the teeth and jaws. The different methods of leverage utilised in extraction by forceps vary according to the nature of the roots and to the resistance offered by the alveolar bone. Thus the operation of tooth extraction must be to some extent stereotyped. Yet in practice we find that there is perhaps no part of dentistry in which there is such a wide variation of method on the part of individual dentists. Manual dexterity and the ease of constant practice count for much; one operator using methods to all appearance heterodox may be far more successful than another who uses the orthodox method. Manuals on tooth extraction, of which there are many, usually represent the practice of the individuals who write them, and since these are generally dentists of large experience, their books have a personal interest often lacking in more academical publications.

This volume may be taken to represent the American methods, which differ from those current among the majority of British dentists. The actual technique employed does not appear always to be the most efficient mechanically, though doubtless, in the author's hands, it yields excellent results. Some of the forceps recommended by Mr. Cahn appear clumsy when contrasted with English forceps. He advises the use of bayonet-pattern forceps for extracting upper incisors. But the straight forceps commonly used in this country, being applied in a straight line with the long axis of the tooth, surely represent the maximum efficiency of force with the minimum risk of fracture, whereas the bayonet type, though admirably adapted for extracting upper third molars, are less mechanically efficient for front teeth. It is curious to find no reference to the use of the straight elevator for the removal of lower wisdom teeth, in the use of which the backward curve of the roots, which offers so formidable an obstacle to the use of forceps, is utilised to facilitate extraction. The statement that no tooth should be extracted unless previously radiographed is surely a counsel of perfection and probably not feasible even in America, where an X ray outfit is much more often possessed by the dentist in general practice than in this country. The use of an elevator for extracting upper third molars appears to us as too dangerous a procedure to be commended for general use. The advice to pack a socket *tightly* for the treatment of hæmorrhage is unsound. It invariably leads to infection of the socket with the risk of secondary bleeding. Packing a socket for hæmorrhage, unless as a last resort, is to be deprecated. The statement that "whole blood taken from a parent, or in urgent necessity, from the operator himself, injected into the patient will stop the hæmorrhage in some cases" lacks the important proviso that the donor must be of the same blood group as the recipient. There is a chapter on blood pressure which contains useful information not generally included in a dental text-book.

THE SPHENOIDAL SINUS.

Le Sinus Sphénoïdal. Par GEORGES CANUYT, Professeur de Clinique Oto-Rhino-Laryngologique, et JEAN TERRACOL, Chef de Clinique Oto-Rhino-Laryngologique à la Faculté de Médecine de Strasbourg. Paris: Masson et Cie. 1925. Pp. 278. Fr.25.

THE introduction to this book contains the surprising statement that the sphenoidal sinus has been neglected in recent years, "secluded in the depths of the nasal fossæ, it has likewise been secluded in the folds of forgetfulness." The authors admit that the anatomy of the posterior sinuses has been thoroughly studied and mention the famous anatomical collection of Onodi, which has been acquired for London, but say that exploration and surgery of the sinus have scarcely entered into the region of current practice. That, at any rate, can hardly be said to be the position in this country, and the authors pay adequate tribute to the work of Dr. P. Watson-Williams, whose method of exploration they have adopted. The anatomy of the sphenoidal sinuses is dealt with very fully, together with their variations in size and shape, and the relations with neighbouring structures; this section is illustrated by numerous diagrams, some of which would be easier to interpret if the plane of section were indicated. Methods of examination and exploration are discussed in the next section; the importance of thorough shrinkage of the mucosa with cocaine and adrenalin is insisted on. The authors would have done well to have given an account of their technique of producing local anæsthesia of the soft palate for posterior rhinoscopy, instead of merely giving a reference to a communication in the *Archives Oto-Rhino-Laryngologiques*; they appear to employ a palate retractor, but do not describe it.

A short description is given of a method of transillumination of the sphenoidal sinus by means of a long light-carrier and a pharyngoscope, but it is rightly stated not to be very reliable. The chapter on radiography of the sinus is among the best in the book and includes details of many different methods and angles of approach; some radiographs are illustrated, taken in the chin-vertex line, which show good definition of the cavities, and the intrabuccal film is also well described and illustrated. Of the surgery of the sphenoidal sinus, two methods of approach are mentioned and fully discussed, the "turbinal" and the "septal" routes; the authors consider that the septal route is the easier and the more surgically precise, but that it has the disadvantage of not giving access to the posterior ethmoidal cells, which often need to be opened with the sphenoidal sinus. No mention is made of the simple opening through the ordinary nasal passages, and the authors do not apparently consider this an efficient method of treatment. There is a good table of contents, but no index; a full and useful bibliography is appended.

TUBERCULOSIS.

Development of Our Knowledge of Tuberculosis. By LAWRENCE F. FLICK, M.D., LL.D., Co-Founder of the Rush Hospital for Diseases of the Chest, &c., Philadelphia. Published by the author at 738, Pine-street, Philadelphia. 1925. Pp. 783. $7.50.

Dr. Flick has produced a monumental volume on the history of tuberculosis, beginning with the Code of Hammurabi written 2250 B.C., and ending with the work of the British and German Royal Commissions on Tuberculosis at the beginning of this century. The amount of material amassed is large, and as tuberculosis meant a different thing to the physician in different epochs of history, the value of the material collected together must obviously vary a good deal. Dr. Flick suggests that the Hebrew race was one of the first to become immunised to tuberculosis and that this racial immunisation gradually extended westward through the Greek race to the Romans. References to tuberculosis in the Hippocratic writings are dealt with fully, as also is the work of Galen. Between Galen and Sylvius there was little real advance in our knowledge of this disease, but from the days of Sylvius onwards the amount of writing on the subject has been truly prodigious. Dr. Flick gives extensive quotations from Morton's "Phthisiologica," and devotes chapters to Sydenham, Boerhaave, Mead, Reid, Stark, and others of the eighteenth century. The latter part of the eighteenth century produced new schools in the work of Baillie, the Hunter brothers, and the early morbid anatomists on the one hand, and in the work of Auenbrugger, the inventor of percussion, on the other, thus creating a new conception of tuberculosis. Throughout the early part of the nineteenth century this work, helped greatly by Laënnec, went steadily on, culminating in the introduction of the compound microscope which made possible the work of Virchow and cellular pathologists, and subsequently that of Pasteur, Koch, and the bacteriologists.

The book has little to say about the statistical side of the development of our knowledge of tuberculosis, and we note with regret the absence of references to the bills of mortality which cast such illuminating light on the study of disease in the early nineteenth century. Nor can we find mention of the work of Pott, Addison, Bodington, and Cornet, all of whom made no mean contribution to the study of tuberculosis. The real difficulty in such a history is that of assimilating and sorting the mass of information, tracing the development of men's minds, and the influence of the various great schools of medical learning through the centuries. The author has not always been quite successful in this respect. The book is, however, a most laborious production and contains much important matter, including long quotations from standard texts.

Midwifery.

Third edition. By Ten Teachers. Under the direction of Comyns Berkeley, M.D., M.C. Camb., F.R.C.P. Lond. Edited by H. Russell Andrews, Comyns Berkeley, and J. S. Fairbairn. London: Edward Arnold and Co. 1925. Illustrated. Pp. 778. 24*s.*

"Ten Teachers" has already made itself so familiar and welcome a text-book of midwifery that it is not surprising to receive a third edition within eight years of the first. No introduction of the book is needed. It belongs to the increasing group of joint compilations, and the greatest pains have been taken to reap the benefits and avoid the disadvantages of this method of book-production. The present edition has been thoroughly revised and the illustrations enriched by a number of new skiagrams. So much work has been done recently on metabolism that the chapters on toxæmias of pregnancy have been largely rewritten and preceded by a brief but very clearly expressed review of normal protein and fat metabolism. Since the last edition the Section of Obstetrics and Gynæcology of the Royal Society of Medicine have investigated the subjects of eclampsia and Cæsarean section and their results are incorporated. The chapters on infant feeding have been remodelled and constitute a clear and concise exposition of the most up-to-date views on this difficult subject.

The whole work is written from the point of view of the student and practitioner and provides just those practical details that the latter needs in his everyday practice. To those who do not already know it the book can be cordially recommended.

The Changing School.

By Philip Boswood Ballard, M.A., D.Litt., Author of "Mental Tests," &c. London: Hodder and Stoughton. 1925. Pp. 332. 6*s.*

In Dr. Ballard's survey of evolution in educational methods one finds the product of long experience and a progressive spirit, with a humour that possesses the essential quality of unexpectedness. A chapter on Floggers, Ancient and Modern, is not without sympathy for the difficulties of the flogger, and draws a satisfactory picture of the change that has taken place since both parent and pupil felt and showed hostility to the work of the London elementary school teacher. Such live questions as the theories of punishment, the utility of formal training, and the teaching of the classics are handled with ample discussion on all sides. Among many fresh points of view is the admission that scholars of to-day are less accurate than those of the 'eighties, with the defence that accuracy in the past was gained at the expense of other useful qualities. Certain chapters indicate that Dr. Ballard writes primarily for teachers, but the book is not pedantic, and provides useful reading for those of us who note, perhaps with misgiving, the disappearance from the school curriculum of such honoured acquaintances as the works of Euclid, or who find that in some other study the young folk of to-day no longer follow paths that we once regarded as hallowed by tradition.

JOURNALS.

Annals of Medical History. September, 1925. New York: Paul B. Hoeber. Pp. 205–318. $2.50.—This, the third number of Vol. VII., contains many interesting articles. The first, by Sir Humphry Rolleston, deals with the life and works of Caleb Hillier Parry, the well-known physician of Bath, distinguished not only by his scientific knowledge, but also by his having been the father of William Edward Parry, the famous Arctic explorer. Caleb Parry received his medical education in Edinburgh, graduating as M.D. in 1777, his thesis being a dissertation upon hydrophobia. In 1778 he married, and in the following year settled in Bath. He soon became successful, and some ten years later was making from £300 to £600 a month. One of his most remarkable pieces of work was a description, published after his death, of eight cases of exophthalmic goitre under the heading "Enlargement of the Thyroid Gland in Connexion with Enlargement or Palpitation of the Heart." For the last six years of his life he was crippled by the effects of a cerebral hæmorrhage, but although his speech was much affected his mind remained clear.—Of other papers, Dr. W. G. A. Robertson contributes one upon the "receipts" of that odd personality Sir Kenelm Digby, privateer, courtier, an original member of the Royal Society, and writer on medicines.—Dr. D'Irsay and Dr. H. B. Allyn write respectively upon the Black Death and the Mediæval Universities, and the Social and Economic Results of the Black Death. As regards the first paper we think that Dr. D'Irsay is in error when he says that the "Universities of Latin Christendom were, in the middle of the fourteenth century, in possession of the Hippocratic Corpus . . . ." There is but little evidence to show that works of Hippocrates other than the Aphorisms and the other treatises commented upon by Galen, De Prognosticis and De Regimine Acutorum, were known at the universities, even at so medical a university as Montpellier circa 1350. Incidentally, the quotation from Hippocrates given at No. 15 of Dr. D'Irsay's bibliography is so full of misprints as to be unintelligible.—Dr. Allyn's paper is interesting, but it would seem that FitzRalph's statement that there were 30,000 scholars at Oxford in his time, and that the numbers fell to 6000, must in spite of Cardinal Gasquet's apparent endorsement be disbelieved, in view of Rashdall's statements in his Universities of Europe in the Middle Ages.—Dr. J. M. Ball writes upon Ether Tragedies in reference to Morton and Wells, and above all to Dr. C. T. Jackson. Jackson suggested ether as an anæsthetic in 1846, and when he found that he had been anticipated by a then unknown country doctor, Crawford Long—who, in 1842, removed a tumour under ether—he gave Long the credit which was his due.—Mrs. Long Tayler, a daughter of Crawford Long, writes a charming account of her father.—Dr. J. M. Hayman gives the text and translation of Malpighi's treatise on the structure of the kidneys.—Among the reviews is an appreciation, well deserved, of three works by Dr. W. H. S. Jones—namely, his edition of two volumes of Hippocrates in the Loeb Library, Malaria and Greek History, and the Doctor's Oath.

Revue d'Actinologie. Paris.—The growing importance of actinology as a branch of medical therapeutics is ample justification for the new French *Revue d'Actinologie*, the second number of which has just been issued. It is appearing at present every three months and is published by L'Expansion Scientifique, 23, Rue du Cherche-Midi, Paris VI. In addition to numerous original articles on the technical, biological, therapeutic, and hygienic aspects of the subject, the editors contemplate including an analysis of all important publications dealing with radiation.

THE LANCET.

LONDON: SATURDAY, DECEMBER 12, 1925.

CRITICISM OF THE GENERAL MEDICAL COUNCIL.

Criticism of the General Medical Council has been the inspiration of articles and letters in many journals of varying status and aim during the past week. We notice appeals in the press, and we have received them at this office, that we should contribute something in the nature of a reply from this journal to the charges which have been levelled at the Council for this offence or that default, and especially for removing certain practitioners from the roll of the medical profession. If only we were allowed to submit the case of a particular practitioner to scrutiny, it would not be hard to collate the facts, as they were laid before the General Medical Council, with the wording of the relevant Acts of Parliament, and then to come to an honest decision, right or wrong, as to the justice of what the Council had done. But unfortunately those who explicitly ask for our views do not confine themselves to the alleged wrongs of a particular practitioner, or even to the exercise, harmfully in their opinion, of any specific function of the Council; nor are the concrete offences or groups of offences which may bring a practitioner under the disciplinary attention of the Council made the subject of a definite complaint. The various articles, like the letters which we have received, are not possibly susceptible of reply, because they start such a multitude of different subjects. In one article fault will be found not only with the actions or attitudes of the Council, but with its constitution and its mode of election; in another the blindness of medical leaders to the virtues of the general mass of practitioners is deplored, and a recipe is given for the production of leaders of a better sort; in another the need of advertisement is dwelt upon in the interests of the public as well as of the doctor. Some ask that the General Medical Council should be composed, to various proportions, of laymen; some that medical members of the Council should be elected by laymen; some that lay members of the Council should be nominated by different lay authorities; and some that all the Council should be elected by the general vote of the various medical activities represented and not by the governing bodies of university faculties, colleges, and corporations. The avowedly hostile critics of the Council are so little unanimous that certain of them can be considered to have answered the accusations of others; but one abstention they display in common—they make little or no reference to the possible spread of abuses which are prevented by the statutory actions of the Council. The Council is described as a "trades-union," a "tyranny," or an "anachronism," but the fact is unacknowledged that without the procedures which the Council has adopted unconscientious doctors might either impose on the public with unwarranted claims, or provide the public with the ministrations of unqualified men, while taking fees for medical services. These procedures are of the highest public value, and in our opinion the fair and fearless way in which the necessary duties have been discharged should have earned the Council public gratitude.

The case of Dr. W. Lloyd has determined most of the recent attacks upon the Council. The case, as presumably all our readers know, is that of a qualified medical man who is held to have secured professional advantages through an article in the lay press, not, however, written by himself. A statement of the case was made in the House of Commons by Mr. Neville Chamberlain last week (see p. 1259) and can be compared with the summaries of the proceedings before the General Medical Council in our own columns and in those of the *British Medical Journal*, when it will be seen that the charge presented certain characteristics, novel in themselves, making it inevitable that a decision against the practitioner would be received with surprise by many. Now there is no action of the General Medical Council which more, and more regularly, excites adverse comment in the press than the exercise of a power which appears to make for suppression of information. This is perfectly intelligible, and this is why all the penal cases, heard by the Council, which have been or have appeared to be on all fours with the case of Dr. Lloyd, have received similar publicity, and to some extent have drawn upon the Council similar opprobrium. There are limits to the criticism of the Council, and it has not been said by anyone that there is no need, in the interests of the public, for any authority to watch over the dissemination of medical information; but when the medical profession, through the Council, supplies that authority its employment is always resented. The critics of the Council seem to consider either that the Council possesses no right to prevent any medical man from communicating any sort of article to the lay press; or that, if the Council has such a right, the right should be withdrawn until the Council is reconstituted, so that the exercise of its authority should have some public endorsement. These deductions are forcible but not logical. In the public interest there must be some way of preventing men who happen to possess medical qualifications, and therefore to be able to speak as doctors, from assuming the position of medical experts and thrusting on public attention details of new treatments, whether devised by themselves or by others. Such proceedings must do, and indeed have done, great harm, while the medical profession, as the only body able to judge of what is new and valuable, should be expected to prevent the raising of false hopes, the exploitation of methods doomed to failure, and even the undue enhancement of individual reputations. And every responsible editor on receiving a communication from a doctor to say that he has discovered a cure acts on these identical principles: he asks a medical man whom he trusts what chances the alleged cure holds out and what professional standing the contributor enjoys. There should be no doubt about the offence committed in cases where a practitioner assumes in the lay press the position of being able to serve the public in some way better than his fellows can. This form of advertisement is a public danger and must be stopped by the Council. But there is another sort of medical article which, when it is published in the lay press, appears to fall under the ban of the General Medical Council, and we admit that we regret the fact. We mean general pronouncements on topics of health, couched in such language that the public is helped practically by reading them, and can understand the directions in which medicine can help them further. Such articles gain in value if responsible signatures are attached to them, and it is the signed medical article from the best sources which the lay press desires, quite naturally, to be able to put before readers. It is thus at one and the same time a good thing and a bad thing that medical articles should appear in the lay press with medical signatures attached, and much of the resentment which has been excited against the disciplinary decisions of the General Medical Council has been due to the non-existence of any methods of discrimination. Ought the Council to be able to exercise a discretion, ensuring that the appearance of articles of public value should not be made the subject of disciplinary supervision, while trusting both the editors and the contributors to be inspired in the circumstances by the wish to benefit the public and not to exploit the individual?

The "Warning Notice" adopted by the Council in 1923 may be held to be abused when the spread of useful information is confused with the arts of the advertiser. That is patently true; but so is it true that, if the Council should attempt to draw up rules indicating that certain articles signed by medical men can be published in the lay press without offence, while other articles, so signed, cannot receive similar treatment, charges of partiality would be immediately made, would be extremely difficult to refute, and would endanger the reputation of the Council for fearlessness—that exact fearlessness which we consider is the quality in the Council which has given rise to so much irritation. It has been indicated that the kind of medical article which might well be published for the general benefit would naturally be written by a leader of the medical profession, and that is obviously the kind of article which the better lay journals require for their readers. Any rules under which these articles should appear to be exempt from the adverse attitude of the Council would be interpreted as ensuring for well-known members of the medical profession a measure of publicity and a security from reproach which are denied to less prominent people. For this reason we cannot believe that any alteration in the practice of the Council could meet the dilemma satisfactorily; while no rules will ever try out the hearts of men. Nor do we see that the appointment by Parliament of any committee of inquiry would assist either the public or the medical profession in the particular circumstances we have been dwelling upon. But the convenience of such an inquiry would be the public ventilation of the circumstances that have led to so much public heart-stirring. If some committee possessing the public confidence, and with a definite category of references, were to make a pronouncement, the disciplinary functions of the General Medical Council might cease to provide regularly an outburst of criticism, which is not confined to the Council, but includes practically the whole medical profession in charges of intolerance.

◆

VETERINARY RESEARCH AND HUMAN MEDICINE.

The story of a South African farm could, it is said, have been told in three words—drought and locusts. But this is by no means the whole of the story; the stock-raiser of experience could add many more chapters on the vegetable and animal pests which used to render his calling such a precarious one. Indeed, most of the minor horrors of farming seem to be rife in South Africa; and yet on the whole the farmers prosper, and the amount of land under cultivation and of stock being raised increases every year. The explanation lies in the help in combating pests and diseases given to the farmer by the Department of Agriculture of the Union through its Division of Veterinary Education and Research. The main laboratories and experimental farms of the Division are at Onderstepoort, near Pretoria, and we give elsewhere in this issue some account of the manner in which a triple function of routine, research, and education is there fulfilled. Anyone who notes the scope of the activities of the Division must be impressed with the important part played by veterinary science in the life of the subcontinent; but however great the needs of the community, it is hardly likely that the institute for veterinary research at Onderstepoort would have been expanded to such a scale had it not been for the fortunate coincidence of the man capable of developing it and the Government capable of appreciating the man. Paul Kruger recognised the genius of Arnold Theiler and gave it full play; later, Milner, Botha, Smuts, and Herzog pursued the self-same policy. The result is an institute of comparative pathology where is being carried out research of importance not only to veterinary but also to every other branch of scientific medicine.

The extraordinary value that work under these conditions may have is easy to perceive. The student of human diseases sooner or later turns to the experimental method. It is inevitable that this should be so. The time must come when the question arises, What would happen if such a reaction were modified in such a way? and the experimenter seeks to produce infection of a laboratory animal. But he is then met with the very reasonable criticism that he is no longer dealing with disease as it naturally occurs. The infections produced in his laboratory animals differ fundamentally from their very inception from those occurring in human beings; the whole course of the disease is different, and the fallacies inherent in this method of investigation may be so great as to render it worthless. It is for this reason that the necessity for the closer study of diseases occurring naturally in animals is so urgent. The elucidation and cure of such diseases as horse-sickness, lamziekte, quarter evil, and the like is of immediate practical importance, but it is still more important for the veterinary scientist to study by the experimental method disease as it occurs naturally. If he wishes to produce active immunity he can work with attenuated living viruses. If he wishes to investigate that enormously important subject the infections of mucous membranes, he has unimpeachable material at hand; he is not reduced to swabbing a rabbit's throat with pure cultures of streptococci, or feeding the creature with bile and typhoid bacilli.

It is thus from a broader point of view than the merely utilitarian that the development of a living science of comparative pathology is so desirable, and it is Sir Arnold Theiler's peculiar merit that he has had the vision to appreciate this. Onderstepoort was founded to meet the needs of the farmers, and nothing is allowed to interfere with the routine duties of the institute. But always the ideal of research has been upheld by the director. To him no routine investigation is so dull and hackneyed that it ceases to ask a question; no problem is either too difficult or too elementary to merit consideration. The whole institute is permeated with his controlled enthusiasm, and it is a research centre of which any country would be proud.

EPSOM COLLEGE.

Dr. RAYMOND CRAWFURD, as Chairman of the Council of Epsom College, addresses our readers with eloquent pertinacity on another page. In dealing with the progress of the College during the past year he acknowledges the support of many additional annual subscribers, and hopes that in the year to follow a still larger number of new supporters may present themselves. We share his hope, for the College does splendid work, and a large subscription list must be always the backbone of the resources necessary to maintain institutions of which it is a fine example. Good fortune in legacies and benefactions is to be welcomed as implying public confidence, but legacies necessarily are accompanied with the loss of good friends, while benefactions when they arrive, though they possess the charm of unexpectedness, have the drawback, from a treasurer's point of view, that they cannot be counted upon. A large and regular income from subscriptions is the ideal of every treasurer, so that plans for improvement and development can be entered upon with the surety that implies not only a successful but an economical carrying-out. Dr. CRAWFURD indicates many directions in which Epsom College is developing and in which provision should be made for further material improvements, but of these none can appeal more directly to medical men than the proposal to build a new infirmary for the school. The present infirmary is not constructed according to the requirements either of modern medicine or up-to-date nursing, and, moreover, is not economical to run. The provision of a new infirmary would cost from £15,000 to £20,000, a serious sum for the contemplation of the College authorities, but one which wider support from the medical profession would soon render available. The best provision for the sick in a population like that of Epsom College, which is increasing under steady success, is a responsibility upon the medical profession which will be recognised readily. It is a point worth noting, moreover, that the present infirmary when vacated would give accommodation to 45 more boys, an addition to the total number of the school which would be a financial economy, bringing in more money and entailing no commensurate cost; admission would also be provided for some 10 per cent. of a gratifying but over-large waiting list.

We may be repeating words which we have written in substance on previous occasions, when bringing before our readers the claims of Epsom College, but it should never be forgotten that the greatest anxiety which the medical man may have is in regard to the education of his children. He pursues a profession which even after an extended period of practice may not enable him to make large savings; further when success arrives, outgoings maintain a proportion which renders wealth a rare occurrence; and any physical incapacity may remove all chances of practice. Everything should be done to ensure education for the children of our colleagues, and that provided at Epsom need fear no comparisons with the work of other big public schools.

ORDER OF ST. JOHN OF JERUSALEM AND THE BRITISH RED CROSS SOCIETY.—At the last meeting of the Joint Council the resignation of Dr. F. N. Kay Menzies as Director of the Council's Hospital and Medical Services Department, in consequence of his appointment as Medical Officer of Health for the County of London, was accepted. At the same meeting Mr. R. H. P. Orde, B.A., was appointed Acting Director of the Hospital and Medical Services Department.

Annotations.

"Ne quid nimis."

CONSOLIDATION OF WORKMEN'S COMPENSATION ACTS.

THERE is good ground for hope that a Bill to consolidate the Workmen's Compensation Acts will pass through Parliament before Christmas. Anyone who tries to work at present with the original Act of 1906, overlaid and interwritten with its many subsequent amendments, has a difficult palimpsest to decipher. Moreover, the whole subject has now emerged from the tentative and experimental state and has been shaped by experience into something recognised as workable and reasonably permanent. It was time, therefore, to restate the law in a convenient form. The new Bill clears away the 1906 Act, the two Silicosis Extensions of 1918 and 1924, the Illegal Employment Act of 1918, and most of the amending statute of 1923. The principal surviving passages of the last-named enactment which the Bill does not propose to repeal are the provisions for amendment (by the Registrar of Friendly Societies) of the scales of compensation under certified schemes, certain provisions as to notification of accidents, and those as to first-aid and ambulance arrangements—these last being matters which belong less to the law of workmen's compensation than to the law of factories and workshops whereof the amendment and consolidation are long overdue. So far as we have been able to check it, the Bill appears to reproduce the existing law with fidelity and to add nothing that is new. Only one minute alteration is discoverable. The Workmen's Compensation (Silicosis) Act of 1918 empowered the Home Office to set up schemes for the payment of compensation by employers of workmen in specified industries involving exposure to silica dust, and added that the Rules Publication Act should not apply to such schemes. The exclusion of the Act as a whole appears to have been an oversight. What was presumably intended was merely that Section 1 of the Rules Publication Act (prior publication of proposed schemes) should not apply. Section 3 (printing and official publication of schemes) was not meant to be ruled out; at any rate, the Home Office has always complied with its provisions. This alteration in the Bill is trivial and technical; we cite it only to show that apparently the sole change in the Bill is the correction of a minute error. The Bill will not pass through Parliament at this crowded period of the session unless it is treated as a non-contentious measure. It will not be so treated unless the fact is known that it merely repeats the law and neither introduces nor immediately invites any substantial change.

SCIENCE AND RELIGION.

THE difficulties between science and religion are no longer of the sort which led self-confident mechanists and those who believed in the verbal truth of Genesis into a hopeless impasse, and no one is much concerned nowadays about the Flood, nor indeed about a good many other things which have from time to time been supposed to constitute the fundamenta of sound religion. To some it even seems that there is now no substantial disagreement in outlook. Organised religion has given up most of its dogmas which came to be at flat variance with ascertained fact, and there is little or no practical difficulty in any man being a sincere physicist and a sincere churchwarden. Easy minds can satisfy themselves with the reflection that religion and science deal with different and discrete compartments of human experience, and that there is no need to mix them up. But this simple pragmatism is shirking what is still a real difficulty. Religion and science both claim, and must needs claim, to be in the end a complete explanation of the world. No dualism will satisfy, and the discussion has developed now into the question whether a spiritual or a physical conception more nearly expresses reality; it progresses into the question whether the two conceptions are necessarily different and, most significant of all, those who take part in it are nearly always trying to find a basis of unification and common agreement rather than to emphasise points of dialectical divergence. At the moment, indeed, there seems to be less disagreement among those who try to cross the border in either direction than among those of either persuasion who keep to their own side of the line; neither science nor religion are harmonious wholes. Their relations to human experience are dealt with from a variety of aspects and with some differences of opinion in a volume[1] recently published. Earl Balfour says little more than that the truth is very uncertain, but the rest of the essays are all solid and provocative reading, and the general summary and discussion with which the Dean of St. Paul's concludes is most helpful. Dr. Charles Singer provides an interesting historical discussion, and the editor, Mr. Joseph Needham, contributes an amusing claim for the supremacy of biochemistry. We are inclined to regard Prof. Eddington's article on the Domain of Physical Science as the hub of the whole discussion: it cannot be followed in detail here, but the pith of it is the suggestion that the mind is more important than has been supposed in prescribing the nature and laws of the physical world, and that by its selection of values the mind may create its physical environment. It looks as if we shall soon progress to a more adequate conception of the inanimate, animate, and spiritual worlds as forming a coherent and consistent whole. Mr. E. Haigh, who has for many years been a teacher of physical science, has written a much slighter, more elementary book[2] on the same theme and indicating the same conclusions. A good deal of the book is made up of quotations from such a variety of writers as testifies to the width of the author's reading, but the method is irritatingly discontinuous to the reader, and Mr. Haigh would have done better to state his argument in his own words. His thesis is that there is no disharmony between religion and science, and that any attempt sharply to separate the physical and psychical fields of experience is unsatisfactory.

LANOLIN IN THE TREATMENT OF EXTENSIVE BURNS.

THAT "lanolin is the application which gives best results in the treatment of extensive and deep burns" is the opinion of Dr. Bellet,[3] médecin-en-chef in the French Navy. Serving in the great Saint-Mandrier Hospital at Toulon, he has had much experience of burns, especially in 1924, when he had under his care the 13 victims of a cartridge explosion in a casemate of *Patrie* in May and 10 men scalded when a steam-pipe burst on board *Courbet* in August. Other forms of treatment he considers unsatisfactory. Picric acid sometimes causes irritation and gives pain later, though it soothes at the first dressing. "Gomenolised" oil, the French equivalent for eucalyptised oil, drains away and leaves adherent dressings. Ambrine is good, but dressing takes a long time and healing does not occur so soon as with lanolin. Pure lanolin is a little irritating in summer, and about 20 per cent. of vaseline should then be added. Its use for the treatment of burns has long been recommended by French surgeons and was fathered by Inspector Girard, who advised Dr. Bellet in the cases reported. The results recorded were satisfactory. Of the ten men from *Courbet* who were scalded by super-heated steam, three succumbed (on the first, second, and tenth days), but the remainder were cured in six weeks, and discharged without contractions, awkward adhesions, scars or limitation of movements. The pain usually involved in dressings was noticeably absent and lesions on the head, face, and hands were sometimes cured within 20 days. Dr. Bellet gives the following account of his procedure: At the first dressing the burnt surfaces and a wide area around must be disinfected. The skin is always dirty, and compresses of spirit-soap will clean it. These are surprisingly well borne at first, and when they have done their work the burns are washed with much boiled water or weak permanganate solution. Blisters are opened, dead tissue is cut away—saving all the epidermis possible—and the wound is washed with normal saline and dried with sterile gauze. Finally, compresses soaked in sterilised lanolin with 20 per cent. of vaseline kept fluid in a water-bath, are adjusted over the burns, and over them is placed gauze and absorbent cotton. Large dressings should be prepared beforehand, to save time and shock to the patient. Gloves, instruments, and dressings must all be sterilised as if for a surgical operation, and this must, of course, be done also at subsequent dressing. At first the applications are changed daily, but there is no pain or bleeding, for they do not stick. After the dressing is removed, and any sloughs taken away, a washing with weak permanganate is followed by another with normal saline; the area around is cleaned with alcohol or ether; the whole is dried, and the dressing is re-applied. If all has been done well, the wounds are dry. The improvement under lanolin is said to be rapid; there is little discharge, and sloughs are quickly cast off. The wounds soon have rosy granulations and in a week bluish islands of epithelium begin to appear and a healing edge to form. And there is generally no surrounding inflammation nor pus.

TUBERCULOSIS IN CHILDREN.

THE statistical work of Mr. Godias J. Drolet is well known in this country, and his recent review[1] of the mortality in childhood during the past quarter of a century in New York City deserves attention. Mr. Drolet states that in 1868 1191 infants died of tuberculosis per 100,000 children under 1 year of age in New York City. Thirty years later, in 1898, this mortality-rate was already down to one-half, or 609, and by 1923 it had been reduced to 94 per 100,000. Taking the deaths from tuberculosis among children up to the age of 15 years, it is shown that the mortality-rate of 136 per 100,000 in 1898 had been reduced to 33 per 100,000 in 1923—in other words, a reduction of 76 per cent. Tuberculous meningitis causes half of these deaths, and pulmonary tuberculosis comes next in the list. Another fact emphasised in the statistics is that abdominal tuberculosis in childhood has not been responsible for such a high mortality as in Great Britain. During the past two years there have been no deaths from tuberculous peritonitis in childhood in New York, which is striking in view of the fact that 98 per cent. of New York milk is pasteurised. Mr. Drolet attributes the more effective prevention of tuberculosis in childhood in America first to the spread of knowledge about contagion, and, secondly, to the improvement in preventive measures, such as increased hospital accommodation, systematic disinfection, and the pasteurisation of the milk-supply, all of which have diminished the risk of massive infection of children with *B. tuberculosis*.

In the same journal[2] Dr. B. S. Herben and Dr. M. A. Asserson make a statistical study of tuberculous meningitis from birth to the age of 15 years, touching first on the vexed question of the portal of entry in tuberculous meningitis. In the series of 115 cases dealt with the authors obtained definite history of contact in 56 per cent., a history of probable contact in 18 per cent. and suspicious history in 10 per cent., and no history in 16 per cent. They consider the theory of milk infection to be untenable in these cases because in New York City 98 per cent. of the milk-supply is pasteurised. The influence of tenement houses, of diseases such as measles and whooping-cough, and of sex and of age are all discussed as ætiological factors. The fact that about 9 per cent. of the cases were preceded by tonsillectomy unassociated with any other disease leads the authors to the conclusion that further research on this line is necessary. The greatest number of cases of tuberculous meningitis in any single age-period was found in children between 1 and 2 years of age, whilst, in terms of absolute numbers only, outside of the American stock there were more cases of tuberculous meningitis amongst the Italians than in any other racial groups comprised in the series. One of the most interesting sections of this study is that which deals with the investigation of housing conditions as an ætiological factor. This lays emphasis on a very valuable point. The part played by zymotic diseases as a predisposing cause is, of course, well recognised, but the connexion with operation for tonsillectomy is an isolated factor in the inquiry which certainly needs further investigation.

---

[1] American Review of Tuberculosis, 1925, xi., No. 4.

[2] Ibid., 1925, xi., No. 3.

At the moment it would appear to be useless to speculate on this point without further data, and especially without controls. That the mortality-rate in tuberculosis in childhood has fallen with such marked rapidity during the last quarter of a century is a demonstration of the value of the antituberculosis campaign in New York.

PERMANENT CARE OF THE FEEBLE-MINDED.

IN the history of social progress in the twentieth century the Lancashire and Cheshire Society for the Permanent Care of the Feeble-minded[1] occupy an honourable position. They were pioneers in obtaining recognition for the fact that inborn mental defect is a permanent condition requiring life-long care, and their colony at Sandlebridge was the first of such establishments founded in England to meet a need even now inadequately supplied. On the occasion of the opening of a new recreation hall in the earlier part of this year reference was made to the remarkable beginnings of a work which is still incomplete. Twenty-eight years ago Miss Mary Dendy, now president of the society, set out to collect evidence which would induce the School Board for Manchester to adopt the then tentative experiment of special schools. First working single-handed, and later with the help of the late Dr. Henry Ashby, she discovered 500 defective children actually in the class-rooms. A further series were so grossly afflicted that school attendance had been excused. "Most of these cases were very severe, and many were pitifully neglected. One lad we found tied up in a cellar naked and howling."

By the time the survey was completed it was realised that special schools were not going to solve the problem. A permanent home was needed and protective legislation to keep the children safe and so to safeguard society from them. The statement of these aims seems obvious to the point of triteness to-day, but in 1897 the opposition aroused was fierce and almost universal. Even mental specialists considered that it was unjustifiable to put a stigma on any child by saying that he could not become normal, even if this was the obvious truth. From discouraging beginnings, however, indomitable pluck and hard work have built up the flourishing colony of to-day. Sandlebridge now shelters 212 inmates over 16 and 108 children. Over 200 adults have been there from an early age, some of them over 20 years. As all who have visited the colony know, they live under admirable conditions. A large farm and market gardens not only supply the older men and boys with a healthy and satisfying occupation, but provided produce for the institution to the value of over £2000 in 1924. Both males and females are trained in a variety of skilled trades which utilise the gifts of all, and make the colony almost self-contained as regards labour, if not financially self-supporting. The school has been extended during the year, but the pressure in places is very great, and speaks eloquently of the need for similar institutions elsewhere. It is disappointing that local authorities should still refuse to exercise their right of maintaining defectives after the age of 16, even though, as in two cases quoted in this report, the lads are of proved criminal tendencies. The instinct of the ordinary man, who revolts against the idea of permanent confinement and demands that the experts should prove their case in every instance, is none the less a sound one. The appeal of Sandlebridge and other colonies will be all the stronger when it is realised that they are required for selected cases only out of the feeble-minded population, and that special schools and home supervision will suffice for the majority. In view of the high reputation of this colony and the indispensable work it is doing, a fall in subscriptions of over £265 for the current year is regrettable. A suggestion that the debt of £3000 incurred for a much-needed recreation room and additional beds should be paid off in commemoration of Miss Dendy's long years of service is worthy of wide support.

ENCEPHALITIS FOLLOWING VACCINATION.

AT a recent meeting of the Académie de Médecine of Paris Dr. F. S. van Bouwdyk Bastiansee[1] and Dr. Terburgh, of The Hague, in collaboration with Dr. Byl, of Utrecht, and Dr. Levaditi, of Paris, made an important communication dealing with the occurrence in Holland of encephalitis following vaccination. During the course of 18 months there had been 34 cases of which 14 were fatal. The first case developed in March, 1924, and was followed by the second in April, the third in July, and five more in September. The next two occurred in February, 1925, the largest number in one month—viz., 16—being notified in March, followed by seven in April, and the last at the end of June. The clinical course was as follows. After a period ranging from 9 to 15 days after vaccination, the interval in the great majority being 10 or 11 days, an acute and violent cerebral condition developed. The first symptoms were vomiting and headache followed by increasing drowsiness. The following days convulsions appeared affecting one side or one extremity only. Babinski's sign was present in all cases in which it could be investigated. In only one case which ended fatally was there any paralysis—viz., hemiparesis accompanied by paresis of the frontal branch of the facial nerve. In the cases which recovered the acute stage lasted from 7 to 15 days. There were no sequelæ. The condition was obviously one of encephalitis, as meningitis could be excluded by the normal condition of the cerebro-spinal fluid, poliomyelitis by the absence of paralysis, and tetanus by the absence of trismus, convulsions, and the characteristic facies. The disease differed from epidemic encephalitis and the ordinary encephalitis of children in the following respects. The great uniformity of the symptoms as contrasted with the variable picture of epidemic encephalitis. The shortness of the acute stage, the absence of paralysis, particularly of the eye muscles, the presence of Babinski's sign, and the absence of sequelæ were distinctive. In two cases in which the brain was examined histologically the lesions were chiefly localised in the white substance, whereas in epidemic encephalitis they are mainly situated in the grey substance with a predilection for the mesencephalon. In some cases the vaccination pustules were very pronounced, but as a general rule the vaccinal reaction was normal. The lymph employed in the 34 cases did not come from the same calf but from ten different animals, and the lymph used for vaccinating these animals was derived from five different sources, two strains being of Dutch origin, one from Berne, one from Hamburg, and one from the Dutch Indies. In discussing the nature of the encephalitis the writers regard the possibility of a vaccinal encephalomyelitis as unlikely, as the vaccine did not show any exceptional neurotropic affinity, and numerous inoculations of rabbits with the patients' cerebro-spinal fluid remained negative. A more likely hypothesis appeared to be the activation of a dormant virus in children who were carriers of epidemic encephalitis. This view was supported by the following facts: (1) Most of the cases occurred at a season of the year when a recrudescence of epidemic encephalitis was to be expected. (2) Attempts to transmit the disease to animals failed, which is the rule in epidemic encephalitis. There was a further possibility of the affection in question being caused by some unknown virus which was capable of producing a particular form of encephalitis under special conditions.

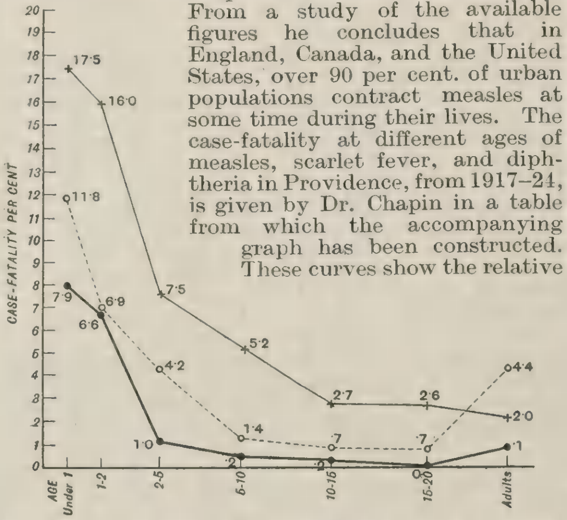
SOME EPIDEMIOLOGICAL STUDIES.

RECENT issues of the *American Journal of Hygiene* contain valuable contributions to epidemiology. In the September number Dr. C. V. Chapin, the distinguished veteran health officer of Providence, R.I., reviews the incidence of measles in that city, 1858–1923. Recently there has been a periodicity of a little over two years, but longer intervals were experienced in the earlier period. Dr. Chapin's comparison between sickness and mortality curves since 1907 clearly shows the inutility of mortality statistics for purposes of public health administration. From a study of the available figures he concludes that in England, Canada, and the United States, over 90 per cent. of urban populations contract measles at some time during their lives. The case-fatality at different ages of measles, scarlet fever, and diphtheria in Providence, from 1917–24, is given by Dr. Chapin in a table from which the accompanying graph has been constructed. These curves show the relative importance as causes of death at different ages of measles, scarlet fever, and diphtheria, and, when checked by a separate statement of the actual number attacked by each disease, indicate the scope of preventive medicine in respect of each disease.



Experience in Providence, R.I., of case-fatality of three chief children's infections.

Diphtheria: upper (continuous) line. Scarlet fever: middle (dotted) line. Measles: lower (continuous) line.

In the same number of the journal is an account of an outbreak of 116 cases of scarlet fever due to ice-cream, traced to a person engaged in the process of manufacture, who was suffering from scarlet fever at the time. A filtrate prepared from a culture of hæmolytic streptococci, isolated from this ice-cream maker, gave typical reactions on persons known to be Dick-positive.

The November issue contains a study of multiple cases of infantile paralysis in 253 families. A large proportion of the so-called secondary cases were found to arise from a source common to them and to the respective primary cases, while a much smaller proportion of secondary paralysed cases in the same family, which occurred within 10 to 18 days after the primary cases, can be regarded as probable true secondary cases. It is inferred that the period of incubation of the disease varies between 10 and 18 days, and that the search for the source of infection should centre round about the fourteenth day before the onset of acute symptoms. It would appear also that the period of greatest infectiousness is within the first three or four days of the acute stage of the disease. The investigators, Dr. W. L. Aycode and Dr. Paul Eaton, make a comparison of multiple cases in households of measles, scarlet fever, and infantile paralysis.

MYOMECTOMY FOR FIBROIDS.

IN an article recently published in our columns[1] Mr. Victor Bonney described myomectomy as the treatment of election for fibroids. By his definition this means that he considers conservation of the uterus the ideal to be aimed at whenever the organ, apart from the tumours, is reasonably healthy. Such an ideal is probably present in the mind of most gynæcologists confronted with a case of fibroids in the child-bearing period; but technical difficulties, uncertainty about the risk of death, and a doubt whether a functionally useful organ may be preserved without risk of recurrence of the growths often sway the mind in favour of hysterectomy. Myomectomy is very frequently done, of course, where there are only one or two fibroids discovered, and these are submucous; but its exponents are not satisfied with this limited use. In the hands of Mr. Bonney good results are undoubtedly obtained, and his contributions to the literature of the subject and the excellent technique and instruments he has evolved will do much to make the operation popular. In a paper read at a meeting of the North of England Obstetrical and Gynæcological Society on Oct. 16th, Dr. Leith Murray, of Liverpool, also gave an encouraging account of 60 cases treated by myomectomy, and deplored the fact that so large a number of women suffer removal of their uterus when it might be saved. It may be objected, however, that the very expert operator who has developed a special technique may get exceptional results, and that the procedure is not one for everyday use. The question of mortality-rate is somewhat vexed at present. In Mr. Bonney's series of 220 cases the rate was nearly 2·1 per cent., which, he considers, compares favourably with that for hysterectomy. Dr. Arthur Giles, however, disputes this view, and states that although he has done 203 myomectomy operations (mainly in women under 40) with but three deaths, his death-rate for the last 1000 hysterectomies has been only 0·6 per cent. Taking also into consideration the possibility of recurrence, he thinks that hysterectomy is certainly the better operation after the child-bearing age is over. At the discussion following the reading of Mr. Bonney's paper at the Royal Society of Medicine, London, at which Dr. Giles made these comments, Lady Barrett said that she had commonly found microscopic myomata in uteri which contained multiple seedling tumours, especially in women of from 30–36 years of age, and that an attempt to remove the seedling tumours would leave the microscopic ones to grow later. But Mr. Bonney considers the fear of recurrence an unsubstantial bogy. The seedling tumour is, he thinks, probably formed much earlier in life than has hitherto been believed—probably in the 'twenties—and the formative agent, whatever that may be, ceases to act after a period. There is at any rate this to be said, that seedling fibroids may not interfere with the physiological functions of the uterus, and myomectomy, which is not effectual in removing all the growths, may tide the patient over till she has passed the child-bearing age, after which the radical operation may be performed. Dr. Murray is convinced that a uterus much mutilated at the operation may undergo involution and heal with a negligible risk of weakness in any future pregnancy, whilst the sentimental value of the conserved uterus and its effect on the later history of the patient is certainly very considerable. All the authorities are agreed that extensive myomectomy may be followed by pregnancy, and that the operation can be done without producing abortion in pregnancy. Dr. Giles has done myomectomy in 18 pregnant women, all but one of whom went to term. But the comment of Mr. Gordon Luker that rest and sedatives are nearly always effective in relieving the symptoms of fibroids in pregnancy may well be borne in mind. Many women do not want children, and until it is proved that no extra risk is incurred by the extended operation the point of view of the patient is obviously very important.

UNIFICATION OF POWERFUL MEDICAMENTS.

THE Second International Conference on the Unification of the Formulæ of Powerful Medicaments was held at Brussels from Sept. 21st to 29th last, when Sir Nestor Tirard represented the General Medical Council, Mr. Edmund White the Pharmaceutical Society of Great Britain, and Dr. G. F. McCleary the Ministry of Health. Prior to the Conference the British delegates held several meetings to discuss the programme submitted, and to draft a document representing their views. The Conference was attended by some 50 delegates sent from 27 powers, several of whom had forwarded reports upon the programme. These were circulated and were reported upon by special committees, and were then discussed at full meetings of the Conference. Of the ten questions in the programme to be considered, one relating to international regulations for the sale of narcotic drugs was withdrawn, as this subject had already been dealt with at a conference of the League of Nations. The other questions were discussed, with results which were embodied in a series of resolutions, of which the more important were these. The Conference advised the recognition of biological methods of standardisation which have been or may be recommended by the Health Section of the League of Nations. It approved of the formation of an International Secretariat for the unification of pharmacopœias, while recognising that the conditions of its establishment must be determined by the League of Nations. Similar reservations applied to the proposed formation of two other international committees for the investigation of assay processes and of methods for making galenical preparations. The British delegates, while in general agreement with the recommendations of the Conference, have notified certain reservations in their report to the Government. These reservations deal with methods of estimation of fluid preparations, with some of the proposed standards, and with some of the proposed alterations in nomenclature. The proposals remain inoperative until officially accepted by the several Governments. It may be said, however, that the nomenclature proposed by the Conference for international adoption does not differ materially from that of the First International Conference and follows closely that of the British Pharmacopœia.

PUBLIC HEALTH ADMINISTRATION.

THE whole question of the Poor-law was considered by a Royal Commission appointed in 1905, which reported in 1909. Majority and minority reports were made, differing on important points, and in 1917 a committee known as the Maclean Committee was appointed "to consider and report upon the steps to be taken to secure the better coördination of public assistance in England and Wales and upon such other matters affecting the system of local government as may from time to time be referred to it." This committee succeeded to a great extent in reconciling the majority and minority reports of the Royal Commission. It recommended the abolition of the boards of guardians and the transfer of their functions to local authorities—normally county and county borough councils—on certain stated lines. The Maclean Report was accepted by the Government in 1919, and last May the House of Commons accepted without a division a resolution to the effect that legislation on the lines of the Maclean Report should be passed, including "a complete absorption of the existing Poor-law authorities and their functions in the county, borough, and district councils." On that occasion the Minister of Health made it clear that, while he accepted the principle of the resolution, he must not be understood as accepting the whole of the proposals of the Maclean Report. He added that it was the intention of the Government to consider the whole question anew, and, following the precedent set in rating and valuation, to discuss it fully with all the local authorities concerned.

Certain provisional proposals have now been circulated from the Ministry of Health to associations of local authorities, the L.C.C., and others concerned as the first step in this process of discussion. Generally they have been drawn up on the lines proposed by the Maclean Committee, but greater freedom is given to local authorities in arranging for the performance of the transferred functions, while new provisions are included with respect to the financial relations between the Ministry of Health and local authorities. These provisional proposals should enable local authorities to offer constructive suggestions of a definite and concrete kind, while it should be clearly understood that the Minister holds himself at liberty to modify or vary them in any particular in the light of the comments or suggestions to which they may give rise.

EXANTHEMA MILIARIFORME.

UNDER this title Prof. M. Manicatide,[1] director of the Pædiatric Clinic at Bucharest, and his assistant, Dr. A. Schiler, report five cases in children, aged from 6 weeks to 4 years, of a new acute exanthem, which was first seen in a creche at Bucharest in 1913, and ten years later in another creche in the same city, when it formed the subject of a communication by Dr. M. Danila and Dr. Stroe to the Société de Biologie of Paris. The incubation period is probably five to eight days, and usually escapes notice altogether, as the only symptom at this time is a slight cough. The invasion, which lasts one to three days, sets in abruptly with fever, profuse sweating, and catarrh of the buccal, pharyngeal, nasal, bronchial, and occasionally conjunctival mucous membranes, though the intensity of the catarrh is never very great. The eruption lasts three to four days and consists of two stages. The first or scarlatiniform stage is characterised by a general or local erythema, and the second by a vesicular or miliariform eruption. The disappearance of the vesicles is immediately followed by desquamation, which is fine and branny in character, sometimes being hardly apparent. When there is only a single crop of rash, the disease is of short duration, but it may assume a prolonged course when the eruption appears in several crops which are either separated from one another by a short interval, or subintrant with coexistence of a scarlatiniform eruption, miliaria, and desquamation. Examination of the blood during the scarlatiniform stage almost invariably shows a predominance of the mononuclear leucocytes. During the vesicular stage the blood returns to its normal condition. General enlargement of the lymphatic glands and increase in size of the spleen are the rule. Exanthema miliariforme must be distinguished from the eruption described by American writers under the name of exanthema subitum, which it resembles by its short invasion and catarrh of the mucous membranes, but the critical fall of temperature coinciding with the appearance of a morbilliform eruption is distinctive of exanthema subitum. The disease which exanthema miliariforme most closely resembles is sweating sickness. The latter, however, is a grave contagious disorder which affects adults, whereas exanthema miliariforme is a mild disease which attacks children only, especially infants, and never their mother or nurse. The prognosis is invariably favourable and the treatment symptomatic.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CLI.—THE TREATMENT OF SPASMOPHILIA.

SPASMOPHILIA is a term which includes infantile tetany, both in its obvious spasmodic forms of carpopedal spasms, convulsions, or laryngismus, and also in its latent forms. In the latter recognition rests on the appearance of Chvostek's facial sign, Trousseau's sign (muscular spasm on pressure over large arteries or nerves), or Erb's sign of increased excitability to the galvanic current. The condition being a symptom-complex rather than a disease the treatment must be directed towards a correction of the underlying error of metabolism or nutrition, as well as towards an alleviation of the more urgent spasmodic symptoms.

The many advances during the past seven years in our knowledge of the factors concerned in the production of spasmophilia are due directly to researches into the chemistry of the blood, made possible by recent developments of micro-chemical methods of analysis. Prior to these but little advance had been made for a hundred years. The treatment advocated in the text-books of 1920 (and even later) differs very little from the sedative, purgative, and hot-bath treatment of the text-books of 1820. It had long been known that there was a close association between infantile tetany and rickets; that tetany was peculiarly prevalent during the winter and spring months; that digestive disorders were a strong predisposing factor. But now we can add to these clinical observations certain facts gathered from experimental and chemical investigations which point us more directly towards the exact nature and causation of the condition. A preliminary re-statement of some of these will make clearer the principles of treatment to be detailed later.

Biochemical Considerations.

1. Measures which lead to an alkalosis increase the spasmophilic symptoms, while the administration of acids has a contrary effect. An example of this is the not uncommon occurrence of a case of mild latent tetany being thrown into active carpopedal spasms by the administration of large doses of alkalies, either by the mouth or in the process of blood transfusion.

2. The rôle of an alkalosis in the production of tetany is confirmed by a study of the examples of tetany in adults which may follow forced expiration and excessive vomiting. In each case the body is being depleted of acid radicles, CO_2 being washed out of the blood in "hyperpnœa tetany" and HCl being lost in the vomited stomach contents in "gastric tetany."

3. The most constant chemical fault in infantile tetany is a diminution of the calcium content of the blood. The normal level is about 10 mg. per 100 c.cm. of blood. If for any reason it falls to a level of about 6 mg. per 100 c.cm. spasmophilic symptoms will result.

4. The calcium content of the blood may be reduced under any of the following conditions: (*a*) Deficiency of calcium in the diet—e.g., use of a too dilute sweetened condensed milk. (*b*) Deficient absorption of calcium from the bowel—e.g., in intestinal indigestion where there is an excessive loss of calcium in the stools. (*c*) Lack of exposure to sunlight—e.g., a seasonal fall of calcium in the winter months has been demonstrated. (*d*) Diseases of the parathyroids.

5. Where a sufficient calcium is available for absorption a restoration of a lowered blood calcium can be brought about or helped by: (*a*) Administration of acids, especially in the form of hydrochloric acid or ammonium chloride. (*b*) Exposure to direct sunlight, or artificial ultra-violet rays. (*c*) Administration of cod-liver oil, when a diet deficient in vitamin-containing fats has been a factor. Treatment based on these points is being found by clinicians to yield satisfactory results. Readers wishing to go more deeply into the subject should consult the writings in recent years of Howland and Marriott, J. B. S. Haldane, Casparis and Kramer, Scheer and Salomon, Adlersberg and Porges, Paton and Findlay, Burns, Gyorgy, and others.

Management of a Case.

Management includes (*a*) general measures devoted to a correction of errors likely to affect calcium utilisation or produce alkalosis; (*b*) emergency measures directed towards a relief of the urgent spasmodic symptoms such as laryngospasm, convulsions, &c. In a mild or latent case general measures will suffice, and should be continued until all evidence of spasmophilia disappears. In a severe case with spasmodic symptoms the general treatment must be promptly instituted and eagerly pursued, and reinforced by some method of local and symptomatic treatment.

General Measures.—In the child's diet and digestion lies the fault in the majority of cases of idiopathic infantile tetany occurring in the winter months, the lack of sunlight acting as an "accessory after the fact." An ample supply of calcium must be provided and any errors of digestion corrected to ensure efficient absorption. After a few hours' starvation, while a purge is being given, a suitable diet of cows' milk should be prescribed or, when possible, breast milk should be given. Additions should be made to the diet of foods relatively rich in calcium—for example, cabbage, turnip, and oatmeal—given in the form of vegetable purée, with the addition of oatmeal gruel. If there is any doubt about the supply of calcium in the diet calcium chloride in doses of 10 to 15 gr. two or three times a day should be added. Intestinal indigestion should be treated on the traditional lines of cutting down the intake of fat and excess of carbohydrates and giving an increased amount of protein. Skimmed cows' milk or protein milk serves as a suitable basis of such a diet. Potatoes, bread, and rice, containing relatively little calcium, should be replaced by vegetable purée, oatmeal, junket, and meat. An initial dose of castor oil should be followed by a daily powder containing calomel, rhubarb, and ginger suitable for the age of the child. Cod-liver oil plays a part in the absorption or utilisation of calcium and should be given in all cases. A teaspoonful of a 50 per cent. emulsion twice a day suffices.

The chief hygienic measure is to have the child nursed as much as possible in the open air and sunlight. The modern fashion of withdrawing children from out-of-doors sunlight to indoor artificial light treatment is to be deplored; but at certain seasons, and in large industrial towns, a daily exposure to mercury-vapour lamp will serve as a useful supplementary method.

Most important, however, of the measures of general treatment is the systematic administration of acids, best given as hydrochloric acid or ammonium chloride. A child of 12 months should have up to half a drachm of acid hydrochlor. dil. (B.P.) diluted in 10 oz. of water in the 24 hours. The acid solution can be suitably given as a diluent to the milk, care being taken not to exceed the proportion of acid to milk which will produce clotting—roughly 1 pint of acid solution to 2 pints of milk. Ammonium chloride is just as efficacious. After absorption the ammonium is converted to urea and HCl liberated. A suitable dose is a drachm, dissolved in 10 oz. of water, to be taken during each 24 hours, or added to the milk.

Symptomatic Treatment.

The chief urgent symptoms of spasmophilia are convulsions, laryngospasm, and carpopedal spasm; success in their relief will be but temporary unless general treatment has been instituted. When called to see a child who has had a convulsion, the first step is to decide that it was spasmophilic in origin. Chvostek's sign (a sudden spasm on tapping one side of the face) will usually decide the diagnosis, but meningitis, polio-encephalitis, pyelitis, pneumonia, and other diseases should be excluded. A hot bath with cold compresses to the head is a valuable therapeutic measure which will almost certainly have been resorted to by the nurse or mother. In the presence of an actual spasmophilic convulsion, preparations should be made for a rectal wash-out and the rectal administration of chloral hydrate while the hot bath is being given. Chloral hydrate is remarkably effective and safe in these cases. For a child of 12 months a dose of 10 to 15 gr. dissolved in water should be left in the rectum after a preliminary washing out. If the child is able to swallow, 3 gr. chloral hydrate should be given by the mouth instead. In refractory cases an inhalation of chloroform should be used. A practitioner called to such a case should take a rubber catheter, a solution of chloral hydrate, and chloroform.

Laryngospasm, or *laryngismus stridulus*, is an urgent spasmophilic symptom; though improbable, it is yet possible that the condition *may* be fatal, the spasmodic closure of the glottis going on to produce cyanosis, convulsions, and death. The child should not be moved until the urgent symptoms have been controlled, since exposure to chill and fright, such as might occur in a cab on the way to a hospital, exercise a deleterious effect. Hot sponges should be applied to the larynx, while chloral hydrate and rectal wash-outs are used. While awaiting the effect of treatment it is wise to confirm the diagnosis, excluding laryngeal diphtheria or impacted foreign body.

The symptoms of *carpopedal spasm* are not necessarily urgent, but usually require active special treatment, leading after a few hours to much pain and discomfort. The child is usually miserable and crying. Successions of hot baths with chloral hydrate or antipyrin should be tried, until the general measures of treatment have produced their effect.

Chronic and Refractory Cases. Parathyroid Treatment.

Almost every case of spasmophilia—i.e., of idiopathic infantile tetany, or "spring" tetany—yields readily to treatment on these lines. In the rare case of persistent or recurrent tetany which resists treatment there is commonly some chronic bowel condition, such as cœliac disease or idiopathic dilatation of the colon, which demands treatment. If, however, there is no chronic intestinal disease to account for it, a disease of the parathyroids may be suspected. I am in no position, however, to say how this can be proved, for in those cases of persistent and recurrent tetany in a child in which I have been forced to this diagnosis, various samples of parathyroid gland had no effect. The whole question of parathyroid therapy in tetany is centred in the problem of the preparation of an active extract. No doubt there will be great scope for its use when this problem is solved, and the recent experiments of Collip and Clarke[1] appear to mark a definite advance. Nevertheless, it is improbable that spasmophilia in infants is due to a parathyroid lesion. If it were so we would not expect it to be so readily curable as it is without the aid of parathyroid treatment.

Special Articles.

AN INSTITUTE OF COMPARATIVE PATHOLOGY IN SOUTH AFRICA.

The scientific quality of communications emanating from the laboratories of Veterinary Education and Research of the Union of South Africa, and of the reports issued from time to time by its director, is well known. The investigations carried out into the causal agencies of diseases affecting animals in the subcontinent, and the large measure of success achieved in eradication and control are of recognised importance to veterinarians and stock farmers throughout the world. With the generous support of successive governments before and since the Union, the Department of Agriculture has been enabled to expand its laboratories from an emergency shed, whence the rinderpest epizoötic of 1896 was studied, into a main institute at Onderstepoort, near Pretoria, with daughter institutes at Grahamstown and Pietermaritzburg, Vryburg, Bestersput, and Ermelo. An account of the detailed organisation of this unrivalled institute of comparative pathology, developed by Sir Arnold Theiler, K.C.M.G., would seem timely, in view of the efforts made within the last few years to foster the systematic study of this branch of science.

The Routine Department.

The buildings of the main institute alone cover some five acres, and the annual budget of the laboratories is over £90,000. Of this sum nearly half is recovered every year by the activities of the Routine Department, under the general direction of Dr. P. R. Viljoen, laboratory products being manufactured on a large scale for sale to farmers at practically cost price. The sale last year of 15,000,000 doses indicates sufficiently the farmers' confidence in the efficacy of the prophylactic and curative medicaments supplied. This confidence is fostered by addresses given by workers in the institutes, who are ready to discuss with farmers any difficulties or complications that may follow the use of laboratory products.

The total accommodation available at Onderstepoort for the various activities connected with the preparation of laboratory products consists of seven laboratories, seven kitchens, four store rooms, two incubating rooms, four packing rooms, and one cold storage room. The number of horses, mules, cattle, sheep, and goats kept in the stables and kraals on the laboratory site for various purposes averages 1500 at a time. These animals are mostly first utilised for the routine production and testing of vaccines and sera, and they then become available for experimental and research work. At the branch laboratories the numbers of animals on hand average 40 at Maritzburg, 550 at Vryburg, 1500 at Bestersput, 600 at Ermelo. Strict control of the movement of all animals is carried out so that intercurrent infectious diseases are immediately detected and steps promptly taken to check their spread. A staff of four officers devote their whole time to the recording of experimental data, commencing with the arrival of an animal at the station, its registered number, every experiment in which the animal is subjected for treatment, every result and clinical symptom, and, where necessary, full post-mortem report being entered on its own chart; thus it is possible, at a moment's notice, to obtain full particulars of every experiment that has been undertaken into any diseased condition. The records include notification of movements of animals from one stable to another, and cross reference given to any farmers' correspondence that may have led up to the initiation of an experiment.

Methods of Conferring Immunity.

Any attempt on a large scale to confer on animals immunity to specific diseases demands considerable ingenuity, even when ætiology is established. The methods used vary from the comparatively simple preparation and distribution of vaccine where the causal organism of a disease is known, to the devising of means whereby immunity may be conferred against a disease, such as horse-sickness, thought to be due to a filterable virus transmitted by an insect.

Vaccines against Diseases of Known Causation.—Where an organism has been isolated the vaccines supplied are for the most part made up of live strains of attenuated virulence. For example, the live spore vaccine prepared from attenuated cultures of *anthrax* on the Pasteur principle, by a method recently worked out in the research department of the institute, gives almost absolute protection for a period of 12 months; indeed, so successful has this product proved that the Union Government last year decided on its free issue to farmers, in spite of the great loss of revenue entailed. The vaccine against quarter evil (caused by a sporulating bacterium) consists in the artificial aggressin produced by cultures; the immunity conferred is not absolute, but protection is afforded for 9 to 12 months. It should be noted, incidentally, that every batch of vaccine prepared at this institute is tested as to potency and value as an immunising agent before being passed for sale. This system of immunity control is one of the features of the organisation. Red water (*Piroplasma bigeminum*) in cattle is due to a protozoon in the blood, which remains there in some latent form after the animal has recovered. The strength of this residual virus fortunately varies in different cases, and the milder strains have been found suitable for use as vaccines without attenuation. On a similar principle is based the vaccine against anaplasmosis (gall-sickness), a disease caused by *Anaplasma marginale.* A strain was found (later called *Anaplasma centrale*) which produces a milder though still typical form of the disease, and immunity derived from *A. centrale* protects against the more severe diseases due to *A. marginale.* The two types of parasite are easily differentiated under the microscope.

Filterable and Ultra-microscopic Viruses.—In diseases of unknown ætiology, the virulence of infective material derived from a sick animal can sometimes be modified by passage through other animals of the same species. This principle is adopted in the preparation of blue tongue vaccine.

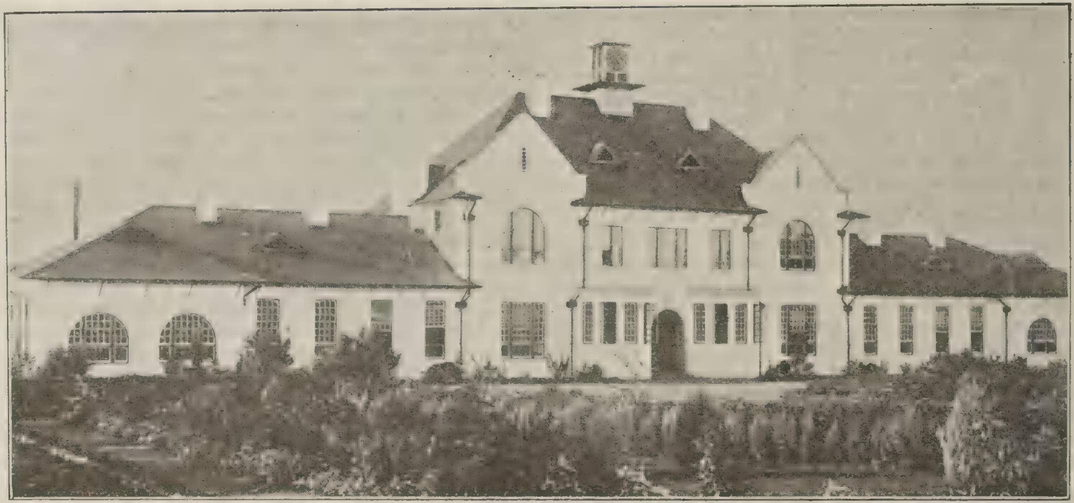
Horse-sickness.—Much more complicated is the system whereby horses, and to a lesser extent mules, are protected against the prevalent disease of horse-sickness. The horse that has recovered naturally from an attack of horse-sickness is called "salted" in South Africa; such animals are rare and are valued highly, since they show a considerable amount of immunity. The immunity is not, however, absolute, breakdowns occurring in seasons when the epidemic takes a severe form; but sufficient immunity can be conveyed to protect most animals against this disease.

Mules and horses differ in susceptibility to this disease and require different methods of conveying immunity. In mules a simultaneous inoculation of serum and virus brings about a fever reaction, and sometimes typical symptoms of horse-sickness. About 3000 mules are inoculated every year, 95 per cent. being subsequently immune; the mortality is 2–3 per cent. In horses two inoculations have to be made with a few days' interval between them, utilising similar serum on both occasions but different strains of virus. Several thousand horses have been inoculated, about 85 per cent. being protected. The scarcity of technical operators has prevented inoculation on a very large scale, but this difficulty is being overcome. Inoculated horses obtain an immunity at least equal to that obtained by "salted" horses, and are in great demand by farmers. In the preparation of serum precautions have to be taken against hæmolysis and against the transmission of infectious anæmia. This is a disease due to an ultra-visible virus easily communicated to horses either by blood or by serum, but experience has shown that if serum is kept for 12 months before use the infective agent is destroyed.

The preventive side of work carried out in the routine department is not confined to the production of vaccines and sera, but is concerned also with the giving of personal expert advice when required, and with distribution of pamphlets offering suggestions as to how by dipping, protection from insects, and by hygiene on farms infection may be further avoided. Knowledge gained from researches in this and other institutes is made available to farmers as soon as possible, and the rationale and limitations of any treatment advised carefully explained to them.

Curative Treatment.—On the curative side less success has been achieved, excepting in regard to the wireworm infection of sheep, for which over 11,000,000 doses of powder (sodium arsenite and copper sulphate) were sold last year. The use of a parasiticide for ticks has been attended with considerable success against the *Trichostrongylus* and *Œsophagostomum columbianum.*

Fig. 1.

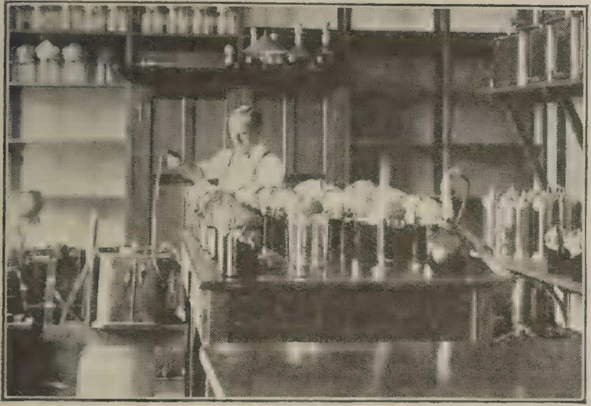


Front view of the main building at Onderstepoort, near Pretoria.

Sufficient dip-testing requisites for about 60,000 tests per year are issued for use with a cheap dip-testing instrument, which enables the farmer to control the strength of dips used for the eradication of ticks.

Diagnosis.—A special staff is available to investigate outbreaks of obscure diseases occurring on farms, however remote. In any case of sudden collapse farmers are urged to send to the laboratories blood smears taken immediately after death, slides being supplied free. To ensure speedy communication a post and telegraph office has been installed actually in the building of the institute; between 50,000 and 60,000 letters, wires, and parcels are received every year and the same amount despatched from the central institute alone. The number of specimens examined approximate to 25,000 every year, and this applies only to microscopical, pathological, and serological specimens, leaving out of account chemical analyses. In addition about 1000 samples each year are received for chemical analysis, partly from farmers in relation to cases such as stock poisoning, partly from other sections of the division requiring chemical assistance, and partly in connexion with the Government Regulations controlling the sale of stock dips and stock remedies. Technical advisory work under these regulations is also carried out. Incidentally in South Africa a curious legal anomaly obtains. There are no antivivisection laws. Any unqualified person may practise veterinary surgery, and anæsthetics are not compulsory for any animal operations. On the other hand, no manufacturer is allowed to sell as a dip or as an internal remedy for any animal disease a mixture which is not accepted by the Government as corresponding to the claims made for it. Patent veterinary remedies are subject to rigid investigation in this institute. No such regulation is applied to patent medicines designed for human consumption.

FIG. 2.



Decanting horse serum.

Farmers are encouraged to forward for tests on experimental animals plants which they suspect of being poisonous. Those which are incriminated are subjected to detailed study in the botanical section of the biochemical department, where a museum of poisonous botanical specimens is arranged for inspection.

Research Activities.

Special blocks are allocated to the study of infectious diseases, pathology, biochemistry, bacteriology, entomology, and helminthology, under the direction respectively of Dr. P. J. du Toit, D.Ph., Zurich, Dr. Med. Vet., Berlin (deputy director of Veterinary Education and Research); Prof. Wall de Rock, Dr. Med. Vet., Berne; Prof. H. H. Greene, D.Sc. Glasgow; Dr. E. M. Robinson, Dr. Med. Vet., Berne; Mr. G. A. Bedford, F.E.S.; Dr. Frank Veglier, Dr. Med. Vet. Turin. Results are published from time to time in the scientific reports of the director,[1] in the *Journal of Agriculture* of the Union of South Africa, and in the appropriate special journals of Europe and America. The following notes do no more than call attention to a few of the problems now being attacked. On the pharmacological side of the biochemical department systematic research is only now commencing, but will mainly concern the investigation of plants directly poisonous to live stock, or responsible for stock disease (e.g., *Cotyledon wallichii*, *Geigeria passerinoides*). On the botanical side studies of the relationship between distribution of plants and occurrence of disease are undertaken. Problems in plant physiology related to nutritive value of natural veld have also formed the subject of laborious investigations by Dr. Marguerite Henrici, Ph.D. Basle, who has recently been appointed research officer in plant physiology. This work includes studies of the chlorophyll content of plants growing under arid conditions, the osmotic behaviour of wilting grasses, plant transpiration during drought, the carbohydrate metabolism of grasses under extreme meteorological conditions, the occurrence of hydrocyanic acid in edible grasses as a phenomenon of wilting, the mineral metabolism of grasses growing in phosphorus-deficient soils. On the more general biochemical side research work has ranged over chemical investigation of poisonous plants; the utility of various compounds for the eradication of external and internal parasites; the fate of ingested arsenicals in the animal body; the chemical changes brought about by bacteria in dipping tanks and the isolation on the non-pathogenic organisms concerned —e.g., *B. arsenoxydans* and *B. arsenreducens*; changes in eggs during cold storage; chemical aspects of deficiency diseases in stock; and a variety of other lines indicated by publications in the reports of the division. The most important work from an economic point of view at present in progress concerns the mineral metabolism of stock, particularly in relation to the "aphosphoriosis in cattle," so widespread over the Union of South Africa. Studies of soil and vegetation are combined with direct nutrition experiments upon the animal itself, both at laboratory headquarters and in the areas over which mineral deficiencies are reflected adversely by the animals, either in the form of specific disease (e.g., styfsiekte), or osteophagia, or generalised malnutrition (stunted growth). In some cases correction of the mineral deficiencies of natural veld has resulted in trebling the growth-rate of calves reared upon it. Results from laboratory experiments on mineral metabolism incidentally yield information upon vitamin factors in stock nutrition; the most interesting fact being that cattle are apparently not susceptible to avitaminoses, but can grow well on rations notably deficient in A, B, and C.

In the helminthological department two officers with their assistants devote all their time to the study of worm diseases. The life-histories of the commoner worms of sheep have been worked out accurately, and methods of combating the diseases are attempted on the basis of the knowledge so obtained. In the bacteriological department, where cultures of bacteria and of trypanosomes are maintained, particular attention is devoted to the study of anaerobes. In the entomological department a good collection of ticks, mosquitoes, flies, and other insects of economic importance is available and their life-histories are being studied.

The Investigation of Specific Diseases.

Nagana.—During the year 1922–23 an agreement was made with the Bayer Company in Germany to test their new remedy, "Bayer 205" on cases of nagana (sleeping sickness of cattle) in Zululand. The company undertook to supply sufficient quantities of the substance and to send their own veterinary surgeon to supervise the experiments. The institute, on the other hand, agreed to supply all the experimental animals and to place the entire staff and equipment of the Nagana Research Laboratory near Empangeni in Zululand at the disposal of this work. The experiments were designed to determine both the prophylactic and the curative action of the drug on infections with *Trypanosoma congolense*, *Trypanosoma brucei*, and *Trypanosoma vivax*. The results obtained do not appear to have been altogether satisfactory,[2] especially in regard to the curative effect of "Bayer 205." However, from the prophylactic point of view fairly encouraging results were obtained. It was further found that by combining treatment by "Bayer 205" with tartar emetic animals could be protected against the bite of infected flies, even though exposed to a very severe infection. It is found troublesome in practice to carry out a series of injections into the jugular vein of cattle, and it is hoped to find a method of treatment which can be given subcutaneously.

---

[1] Ninth and tenth reports of the Director of Veterinary Education and Research, Government Printing and Stationery Office, Pretoria, 1924, pp. 823, 10s.

Lamziekte.—Sir Arnold Theiler's own researches into diseases caused by piroplasms (*Theileria parva*, *Gonderia mutans*, *Anaplasma marginale*, &c.) and into the diseases of ultra-visible origin (horse-sickness, blue tongue, and heartwater) are classical. More recently the complete elucidation under his direction of the causation, prevention, and cure of the mysterious disease of cattle known as *Lamziekte*, as a typical instance of the fine work accomplished in this institute, may be considered in some detail. The chain of causation as unravelled by the director and his colleagues is shown clearly in the Fig. 3, which is largely self-explanatory. Low phosphorus content is a feature of South African soil; over wide areas of the Union the level of phosphorus reached in the natural vegetation is below the physiological optimum of cattle. Cattle attempt to supplement the deficiency by eating dead animal carcasses, often infected by specific saprophytic bacteria which produce a toxin causing the disease known as lamziekte. The deficiency not only leads indirectly to disease, through the pica induced in animals reared on such soil, but also limits their growth, damages their general condition, and diminishes their milk yield. Further experiments are in progress on the mineral metabolism of stock, and it is expected that considerable light will be thrown on other obscure nutritional disorders encountered in practice.

FIG. 4.

The Students' Hostel.

Heartwater.—In 1923 the director of the Rockefeller Institute suggested that one of his staff should visit the institute for the purpose of comparing pathological conditions of animals found in other parts of the world with those prevalent in South Africa; accordingly Dr. E. V. Cowdry arrived at Onderstepoort in June, 1924, and left early in 1925, for the purpose of studying heartwater. The results of the investigations led to the discovery of rickettsia as the cause of heartwater, thus relating the South African disease to the Rocky Mountain fever of America. It is hoped that his visit will lead to an interchange of officers between South Africa and the United States, an arrangement which should react beneficially on the progress of comparative pathology in both countries.

Veterinary Education.

In 1920 educational duties were undertaken for the first time and blocks of buildings, including students' laboratories, lecture theatres, and a students' hostel (Fig. 4), were opened. The course extends over five years leading up to the degree of Bachelor of Veterinary Science (B.V.Sc.) in the University of South Africa. The Doctorate (D.V.Sc.) is attainable not less than two years after qualification by those engaged in research work, and not less than four years after qualification by practising veterinary surgeons on submission of a suitable original thesis. The first two years of preliminary scientific studies are taken at one of the colleges of the University of South Africa or at the Witwatersrand University, while the three vocational years are spent at Onderstepoort.

It is stated that, partly owing to the fact that B.V.Sc. graduates in Government service are now graded on a scale commensurate with the length, severity, and expense of the curriculum, the class of students attracted is very good; this enables a high teaching standard to be maintained. Inquiries are constantly being received from various sources concerning the facilities offered to foreign graduates who desire to specialise in subtropical veterinary science, and the question of running a special postgraduate course for overseas veterinarians is under consideration. An advantage to students is that all the professors and lecturers are primarily research officers with ordinary official duties cognate to the subjects they profess. Preparation for tutorial duties is made outside official hours; teaching officers are graded £100 per annum higher than ordinary officers if of lecturer rank, and £200 higher if of professorial rank. In this way the five professors and eight lecturers are provided at the cost of only two full professorships at any of the Colleges of the University; at the same time teaching is conducted by specialists who, in turn, benefit by the need of keeping themselves up to date over the whole range of their particular subject.

---

[2] Journal of the Department of Agriculture of the Union of South Africa, December, 1924, p. 530.

The system is obviously economical and appears to be working well; indeed, it is held that the advantages of grafting the Veterinary Faculty of the University of South Africa on to the pre-existing division of veterinary research are becoming more apparent every year. Most of the required post-mortem material, embryological material, clinical cases, and the like, are obtained as by-products of the research and routine activities of the division; medical and surgical wards for domestic pets and operating theatres are provided for the benefit of students. Inasmuch as the staff, equipment, and material are already necessary for official work irrespective of the veterinary faculty, the resources for the training of students and post-graduates are exceptional in a new school. This institute should secure recognition as one of the primary centres in the British Empire for the teaching of tropical and subtropical veterinary science, and for post-graduate research work in comparative pathology.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.*

(Continued from p. 1124.)

Official Evidence (Q. 23830-24024).

Mr. Brock and Dr. Smith Whitaker continued their evidence and were asked whether they would favour the provision of the services of doctor and midwife as a first charge on the money available for maternity benefit. Mr. Brock said :—

> The present cash benefit is popular, and any change which made the provision of midwives or doctors a first charge on the money available would not be readily accepted by the insured population, unless it left at least a substantial balance in cash in addition to the services in kind.

In general, with regard to this benefit and the question of linking-up the various arrangements for maternity services, the witness said that there was a great deal of overlapping and probably a good deal of waste, and it would be most desirable, if it could be arranged, to have a scheme that brought the family doctor, the midwife, the specialist, if necessary, and all the services that are available at the maternity centre under a common scheme and a common control, so that they each played their proper part and were brought into proper relation with one another, helping one another instead of acting at a distance as they do now. The difficulty was how the finance could be arranged.

Dental Services.

Mr. Brock agreed that dental treatment as a statutory benefit was most desirable if the money could be found. Something like three-quarters of the industrial population were suffering from dental defects, and the experience of societies giving dental treatment as an additional benefit gave ground for hoping that systematic dental treatment would lead ultimately to a reduction of sickness benefit claims. As from the beginning of this year schemes were in operation under which societies allowed free choice of dentist.

With regard to the scale of fees which would be in force for a national scheme, Mr. Brock said :—

> Unless the scale is sufficiently generous to attract the men of better standing, you will not get the level of work which is really desirable. It would be unfortunate if insurance dentistry came to be looked upon as the cheapest and nastiest form of dentistry.

The cost of a complete service could not be very closely estimated because it depends not only on the extent of the need, but on the extent of the demand. It was thought, however, that 6*s.* per insured person per annum would be the lowest figure at which it would be safe to estimate the cost of a comprehensive dental benefit which did not provide for any contribution on the part of the insured person.

On the question of contributions towards the cost by the patients, the witness said :—

> Any contribution by the insured person is always open to the objection that it will have the effect of ruling out the most necessitous class. Probably the great majority of insured people could afford to find £2 towards the cost of dentures, and the experience of the dental hospitals where they generally require a contribution to the denture cost is that in nearly all cases the money is ultimately forthcoming.

Cases of hardship might be met by the application of the surplus funds of societies to this purpose as an additional benefit.

With regard to dental clinics, the witness said that the economic advantages could only be secured in urban areas; if any system of consultant centres were established, it might be possible to combine dental centres with them. On other aspects of a dental service Mr. Brock said that the service would not lend itself to payment on a capitation basis, and that negotiations in regard to such a service could best be carried on with a joint committee (if one were set up) of the British Dental Association and the Public Dental Services Association.

Optical Treatment.

On the question of the conflicting evidence on the subject of sight testing from representatives of the medical profession and opticians respectively, Dr. Smith Whitaker said that the Ministry had themselves found on an independent examination of the question that the evidence was very conflicting. There were difficult cases of errors of refraction without any other disease of the eye, or disease of the body generally, which required the use of methods of examination which should only be carried out by people who have had a complete medical training.

> On the other hand, there is a general impression, certainly among laymen, shared, I think, by some members of the medical profession, that quite a considerable proportion of cases of visual defects, particularly in elderly people, can be, and in fact are, being treated without any obvious injury to the patient by people who have had no medical training, and in some cases even by people who have not had the special training in the measurement of refractive errors that some sight-testing opticians have received.

The difficulty was to measure the amount of risk that really arises through such cases being treated by people who have not had a medical training.

The Board of Education have had to consider this question in connexion with the inspection and treatment of school children, and they have adopted from the beginning the policy of employing, for the diagnosis and treatment of errors of refraction, medical practitioners only who have had a special training in sight testing. If the responsibility were assumed by the State or by any public authority of providing a public system, the question would be whether they could safely adopt any other policy than that which the Board of Education has adopted.

The question of qualification in eye work for men who have any kind of surgical aptitude at all is mainly a question of their being able to get the requisite amount of experience.

---

* References to the paragraphs in the printed statements issued as appendices to the reports of the oral evidence are given thus: "App. X. 69," and references to the oral evidence thus—Q. 1369.

> Most doctors . . . are potentially qualified, and if the work were there to be done, they would soon become really qualified. You do not need for the testing of errors of refraction the special skill of an ophthalmic surgeon who undertakes all kinds of delicate operations on the eye.

Asked whether ophthalmic benefit, including the provision of glasses, could only be included amongst the normal benefits available to all insured persons as part of a large scheme for the extension of medical benefit to include a specialist service, the witness said that that would doubtless be so if the benefit were to provide for the treatment by specialists of all diseases and injuries of the eye, but it was thought that—

> An ophthalmic benefit that was restricted to the treatment of errors of refraction, including the provision of glasses, might be brought within the scope of medical benefit independently of any general inclusion of specialist services, and it would be worth providing if the money were available, even although other specialist services were not at the same time made available.

The cost on the basis of 6*d.* an insured person would be under £400,000 a year.

Nursing Service.—Massage.

With regard to a domiciliary nursing service, the witnesses expressed doubt whether a service could be provided of sufficient value to justify the application of funds which might be applied in other directions where at present there was no organised service. In the case of nursing, the district nursing associations already covered the ground to a very considerable extent. The societies had shown little disposition to apply their surpluses in the recent valuation towards schemes for nursing services.

Dr. Smith Whitaker said there could be no doubt as to the value of massage and electrical treatment, particularly for cases of after-effects of injuries and rheumatic conditions by which a large amount of prolonged incapacity for work is produced. If funds would permit of such a service it would be more economically and efficiently provided as a part of statutory medical benefit rather than as a separate service given by the Approved Societies.

Insurance Committees.

With regard to the criticism of the Insurance Committee system, Mr. Brock said that this seemed to be well founded. The representatives of Approved Societies on the Committees, to a large extent, are lacking in experience of public administration, and the effective work of committees had become so limited in range as to offer little inducement to public-spirited people to serve.

> If you give them more work to do, say an extension of their general health duties, you bring them into competition with the other local health authorities, and you also tempt them to undertake work in which they really need the guidance of the sort of expert medical staff that the local authority has and which the Insurance Committee has not.

Mr. Brock made it quite clear that the work of the Insurance Committee staffs was in a different category.

> The Insurance Committees' staffs have done their work exceedingly well, and I want to make it quite clear that, while I cannot dissent from the general criticism of Insurance Committees, I do want to pay my tribute to the efficiency of the work of their staffs.

With regard to the future of the Insurance Medical Service, Mr. Brock said :—

> We think a transfer of the powers and duties of Insurance Committees to the appropriate committees of the county and county borough councils would have the great advantage of being a step towards the coördination of all local health functions which is generally recognised as the logical corollary of the coördination of central health functions in the Ministry of Health. It would certainly facilitate coördination between insurance and other public health services, and it would secure the independent expert advice of the medical officer of health and other medical officers of the councils. We should agree that if the functions of Insurance Committees are to be transferred to the councils, then, whatever committee is charged with these duties, it is desirable that it should contain a strong co-opted element, including adequate representation of the doctors.

Other Points relating to Medical Benefit.

The present capitation fee is 9*s.*, and it was not thought that any further inquiry would be likely to lead to a different result. The cost of drugs for the insured population was rising, and the biggest factor in the rise was increased frequency in prescribing in which undoubtedly there was some element of waste.

As to the distribution amongst doctors of that part of the medical pool which related to insured persons who have not selected a doctor, it was pointed out that the great bulk of these were new entrants who very often postpone their choice until they find themselves in actual need of treatment.

As to limitation of numbers on doctors' lists, Mr. Brock said :—

> Our experience does not suggest that there would be any danger in reverting to the previous limit of 3000 for a practitioner working single-handed, but we see no reason for revising the present figure, which was arrived at by agreement between both parties. . . . We do attach importance to a strict limitation of the number of assistants to be employed in order to prevent the farming out of insurance practice.

The unrestricted right of any qualified medical practitioner to be admitted to the panel ought, in the opinion of the Ministry, to continue. Objection to a doctor's inclusion on the ground of his bad record might bring the Committee into conflict with the General Medical Council.

> It is perfectly true that doctors are from time to time removed from the medical list for offences which the General Medical Council may not regard as justifying removal from the register, but these are definite acts in relation to insured persons which have to be established before a competent committee of inquiry. This is quite a different thing from objecting to a doctor on the general ground of his conduct at some time in the past when he was not subject to any disciplinary control apart from that of the General Medical Council.

The suggestion which had been put forward that a doctor's admission to the list should be conditional on the provision of satisfactory surgery accommodation was not well advised, because the standard of adequacy must depend upon the number of patients for whom the doctor accepts responsibility. Until he has come on the list he can have no insured patients, and the adequacy of his surgery accommodation cannot in fairness be considered except in relation to his actual obligations.

THE MEDICAL INSURANCE AGENCY.

A MEETING of the Committee of Management of the Medical Insurance Agency was held at the House of the British Medical Association, Tavistock-square, W.C., on Dec. 2nd, Sir Humphry Rolleston, the Chairman, presiding. A report of the work of the Agency during the year ending Dec. 31st, 1924, to which a financial statement was appended, was read by the Chairman, and showed that during the year under review the Agency maintained its regular progress ; the high standard of former years in new life business transactions was repeated, while in motor-car insurance there was a steady increase, principally due to the special policy which the Agency has been able to secure on behalf of medical men. There was a substantial increase in rebates in all branches except that of Employers Liability, the figures showing a direct benefit to medical men and women insuring through the Agency. After the payment of income-tax, a claim for which was settled under protest, there remained for the year 1924 considerable increase in surplus to be carried to the Medical Benefit Account.

An interim report was received from the Secretary covering the first nine months of the current year, and during this period the rate of progress was more than maintained. The Agency introduced during the first nine months of 1925 no less than £134,400 in insurance, spreading the insurances over first-class companies.

Other business of the Committee consisted in the election to its body of Dr. R. A. Bolam and Mr. Bishop Harman, and the appointment of two useful subcommittees. The first of these, the members being Dr. H. A. Des Voeux, Dr. R. A. Gibbons, and Mr. Bishop Harman, was authorised to consider the future of the Agency and to draw up a scheme, if found advisable, for its incorporation into a Limited Liability Company; the members were empowered to take the necessary legal advice. The second subcommittee, composed of Sir Humphry Rolleston, Dr. R. A. Gibbons, and Mrs. Arthur Ormond, was appointed to consider and report upon the best use of the Girls Education Fund, and it was decided that for the ensuing year one member of this subcommittee should be elected from among the members of the Committee of the Royal Medical Benevolent Fund Guild.

The result of two full years' working of the Scheme for Technical Advice on the purchase of motor-cars, existing between Messrs. Mann Egerton and Co. and the Agency, can now be seen, and in the report the thanks of the Agency were expressed to their consulting engineers for the able manner in which so many difficult questions had been handled.

Grants to Medical Charities.

The Committee resolved that out of the balance standing to the credit of the Medical Benevolent Account, the following grants should be made :—

	£	s.
Royal Medical Benevolent Fund	525	0
Royal Medical Benevolent Fund Guild ..	525	0
Epsom College Benevolent Fund	525	0
(This grant was divided by the Committee in such a way as to leave a grant in the name of Sir Dawson Williams of £105, and a similar grant in the name of Sir Squire Sprigge)		
Educational Grants (Girls Subcommittee) ..	210	0
B.M.A. Charities Fund	157	10
Royal Medical Benevolent Fund Christmas Appeal..	52	10
Royal Home for Incurables, Putney	52	10
Birmingham Medical Benevolent Society ..	26	5
THE LANCET, Editor's Discretionary Fund ..	26	5
Total..	2100	0

As a result of this distribution the total sum subscribed to medical charities by this Agency since 1910 has exceeded £14,000.

Special Grant to Agent.

A grant of £105 was made to Mr. P. N. Adamthwaite to mark the Committee's pleasure at the success of the Scheme for Technical Advice.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Dublin Hospitals and Workmen's Compensation.

THE Dublin hospitals have been forced by circumstances in the past few years to look carefully into the possibility of recovering the expenses of patients' treatment if anyone can be made responsible for such expenses. A special problem is presented by the case of workmen to whom accidents occur in the course of their employment. These patients receive free treatment, often extending over weeks or months, and, eventually, many of them recover damages from their employers. The award is supposed to cover expenses of treatment, but the hospital bill is rarely paid. Dr. Horace Law, on behalf of the Board of Associated Clinical Hospitals of Dublin, put this case before the Committee on Workmen's Compensation last week. He pointed out that the main provision of medical and surgical treatment for cases coming under the Workmen's Compensation Acts had for many years been made by the voluntary hospitals, and that there was no provision for hospital expenses in the case of accident or illness in the course of employment unless (1) the worker had arranged for it by previous payment in trade-unions or guilds; (2) paid himself for his maintenance in the hospital; or (3) the employer had subscribed to the hospital. There was no power to compel the employer or the insurance companies who had insured the employer to pay direct to the hospital or to contribute to the payment for the maintenance of the patient in hospital.

Regius Professor of Physic in Dublin University.

Dr. T. G. Moorhead, King's professor of materia medica in the School of Physic, has been elected Regius Professor of Physic in the University of Dublin, in place of Dr. J. M. Purser, resigned. Dr. Moorhead had a brilliant course in the school, winning exhibitions and scholarships and the Medical Travelling Prize. Having taken his degrees in 1901, he spent a year as chief demonstrator of anatomy in the school, and in 1902 was appointed assistant physician to Sir P. Dun's Hospital. In 1903 he became physician to the Royal City of Dublin Hospital, and in 1921 he was elected King's professor of materia medica. He has long been recognised as one of the leading teachers and clinicians in the Dublin school. He is still a young man and may be expected to bring energy and vision to the duties of his new post.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Formal Opening of the University of Paris.

ALL faculties of the University of Paris assisted at the formal annual opening of the University on Nov. 28th. It is the custom at such openings to announce the University's awards of honorary degrees. At the opening for this year those receiving the doctorate, *honoris causâ*, were Sir Ernest Rutherford, Mr. de la Vallée-Poussin, Prof. Edwin R. Seligman, Sir Paul Vinogradof, Signor Ettore Pais, Sir Edmund Gosse, Dr. Noguchi, and Prof. Pavlov. The work of Rutherford in radioactivity, that of Noguchi, of the Rockefeller Institute, New York, in yellow fever, vaccinotherapy, and serotherapy, and that of Pavlov in gastric physiology are well known in the field of medicine. The other names represent mathematics, economics, jurisprudence, archæology, and literature. As usual, the university ceremonies presented a mediæval setting of gorgeous gowns, hoods, and caps, and armoured men-at-arms.

The Entry into the Medical Profession.

During the academic year 1924–25 there was a slight diminution from the preceding year in the number of diplomas of doctor of medicine granted by the Medical Faculties of France—namely, 1047, as compared with 1123. The distribution over the various medical schools was as follows: Paris 481, Lyons 139, Bordeaux 123, Montpellier 103, Toulouse 53, Strasbourg 41, Lille 33, Algiers 31, Beirut 22, and Nancy 21. These numbers represent only the State diplomas, and do not include 93 university diplomas granted to foreigners, which do not entitle the holder to practise in France.

Poisoning by Carbon Monoxide.

As winter has brought with it the necessity for the use of coke stoves, several cases of poisoning by carbon monoxide have occurred. In one case-group three persons died from such poisoning, induced by defective ventilation in a chimney. In a second example, a man and wife were found dead in bed, the poisoning having apparently been produced by a worn-out stove, the carbon monoxide pouring into the room through cracks and holes in the casing. The two deaths of the second case-group constituted the subject of a striking demonstration made by Prof. Balthazard, who conducted the autopsies at the Institute of Legal Medicine, which replaces the former Morgue of literary and historic fame.

Annual Meeting of the Grancher Clinic.

The annual meeting of the Grancher antituberculosis clinic was held on Nov. 28th. This clinic has become known internationally in the field of tuberculosis. Madame Pasteur was formerly the president of this endeavour. Her daughter, Madame Vallèry-Radot, is now president, thus continuing the noble traditions of the Pasteurs. At the meeting Dr. Calmette delivered an eloquent address, in which he emphasised the economic value of preventing, rather than treating, tuberculosis.

The sale of stamps for raising money to aid the antituberculosis campaign has been launched for the first time in France. It will be tried out by the National Committee of Defence against Tuberculosis in the Département of Meurthe-et-Moselle.

Insulin and Pregnancy.

Pregnancy is not welcome to diabetic women. Obstetricians have often counselled abortion in such cases, as the evolution of the ovum may be abnormal, hydramnios is frequent, and the size of the products of conception often excessive. As a rule, the fœtus succumbs either in the course of gestation, during labour, or shortly after birth. The effect of pregnancy on the diabetic subject herself is often bad; the disease tends to become aggravated after the sixth month, and death in the puerperium or soon after is not rare. Prof. Marcel Labbé and Prof. Couvelaire have reported to the Academy of Medicine a case which demonstrates how completely the exhibition of insulin has changed the outlook. With insulin a diabetic woman, who would otherwise have aborted or died of acidosis, may go on to term and give birth to a healthy child. Women with diabetes should avoid conception if they can, but should pregnancy occur a strict dietary and the skilful administration of insulin may bring about a happy issue.

Death of Prof. Wallich.

Prof. Victor Wallich, of the Faculté and Académie de Médecine, died on Nov. 29th at the age of 62. Dr. Wallich made many valuable contributions in pathology, obstetrics, physiology, and serotherapy, and was especially active in the field of puericulture, where he served as a pupil of Pinard. In his teaching he utilised cinematographic films. His death leaves a vacancy which will not be easily filled.

Male Responsibility in Infanticide.

In consequence of a recent trial at Paris, in which a young woman, seduced and deserted, had killed her new-born infant, and the legal penalties were abrogated, a movement was initiated for legislation designed to extend to the male responsibility in such cases. The new movement has taken the form of a resolution which, it is hoped, will pave the way for formal legal action.

Increasing Pensions in War Disability.

As now exercised, the French veteran pension laws do not fully provide appraisement of 100 per cent. disability for certain cases in which, nevertheless, the disability is total. The cases referred to are those of tremor and other neuropathies. A movement is now progressing to permit such cases to be assessed at the full disability of 100 per cent., and thus to receive adequate monetary allowance. The new movement does not extend to cases where re-education is possible.

"12 bis."

In the official list of notifiable infectious diseases puerperal fever and ophthalmia neonatorum are at present included under the same number—"12." This grouping has been found to stand in the way of trustworthy statistics being compiled, and hence of proper prophylactic measures. For this reason, on the representation of the Medico-Chirurgical Society of Bordeaux, the Academy of Medicine has decided to urge the Minister of Hygiene to make ophthalmia neonatorum notifiable under the number "12 bis."

Dr. Jacques Forestier, of Aix-les-Bains, well known for his work in radiology in collaboration with Prof. Sicard, has been invited by the American Radiological Association to visit the United States, where he will deliver a series of lectures on recent advances in radiology.

In a thesis on drug addiction, presented to the Academy of Medicine, Dr. Tardieu mentions a case of suicide due to veronal ingested in *coquetels*, the term applied to a beverage in common use in the neighbourhood of Bordeaux. French papers are claiming priority in the "cocktail" for the Bordelais.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following table gives some of the 1924 statistics for a group, composed of one city, one borough, and seven county boroughs. The low birth-rates and high neonatal mortalities in the "mill" towns attract attention, especially when compared with towns in mining areas like Sunderland and Wigan, where the total infant mortality-rate is not low.

Name of town.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Cardiff C.	226,400	21·6	12·1	1·52	1·13	2·6	28	78	5·3
Sunderland C.B.	165,100	25·9	15·0	1·42	1·06	4·2	34	101	4·4
Bolton C.B. . .	181,100	17·6	14·0	1·12	1·34	3·3	36	92	7·8
Oldham C.B. . .	147,300	16·3	13·7	1·20	1·41	3·3	51	111	2·9
Bury C.B.	56,830	15·5	14·7	0·93	1·72	3·4	38	71	4·5
Wigan C.B. . .	91,180	21·9	14·3	0·92	0·76	3·9	31	107	6·0
Derby C.B. . .	133,700	19·2	11·3	1·03	1·29	2·0	25	62	1·9
West Bromwich C.B.	78,730	23·6	12·2	0·86	0·99	3·6	40	89	2·2
Nuneaton B. . .	44,620	21·6	9·7	1·03	0·98	1·6	36	59	7·2

C. = City. B. = Borough. C.B. = County Borough.

Cardiff.

Dr. Ralph M. F. Picken reports that the increased prevalence of encephalitis lethargica has not yet affected Cardiff. Only ten cases came to the knowledge of the health department, and cases appear to have been equally scarce in Swansea, Newport, and Merthyr.

Last year a chart was included in the report showing the upward tendency of the mortality from pulmonary tuberculosis in Cardiff, a tendency which Dr. Picken has not traced in any other large city. Although the mortality was a little lower in 1924, the rate is high compared with other large towns. Thus among the 17 largest towns of England and Wales during 1924 Liverpool heads the list with a rate of 1300 per million from pulmonary tuberculosis, and Cardiff comes second with a rate of 1276, Sheffield being lowest with a rate of 821. For all forms of tuberculosis Cardiff was worse than Liverpool and was highest of all those towns with populations exceeding 200,000. Up to now Dr. Picken has been unable to account for this by any cause relating to the nationality or origin of the population, or their age-distribution or any climatic or environmental factor operating in the city. The occupational table, however, of newly notified cases of tuberculosis, which is given for the first time in the report, shows a very high proportion of seafaring men. Thus out of 221 males notified for pulmonary tuberculosis 47 were seamen. The only other occupations which reached double figures were clerks, typists, &c., 19, and labourers, 30. Of the 63 notified male cases of non-pulmonary tuberculosis the occupation of seamen furnished 9, while there were 13 children of school age and 14 children under school age. The figures somewhat confirm the remarks of Dr. Howard Jones in his report to the Newport Port Sanitary Authority. Dr. Picken reports a decline in the number of new cases at the V.D. clinics at the Royal Infirmary and the Seamen's Hospital. The figures have shown for some time that these centres do not attract the innocently acquired cases among women and children. To meet this difficulty special clinics are to be held at least twice a week in connexion with the maternity and child welfare scheme.

The Cancer Local Advisory Committee met towards the end of 1924 and drew up a plan of campaign. With the coöperation of the management of the infirmary it is hoped shortly to complete a statement showing the remote results of operations for cancer of the breast over a number of years. Voluntary notification has been adopted and a leaflet on cancer of the breast has been issued, pointing out to women the importance of consulting a doctor at once if any swelling or lump in the breast is noticed. The antenatal clinic, conducted jointly by the local authority and the Royal Infirmary, was opened on Dec. 18th, 1924, and at the time of writing bids fair to justify the hopes entertained as to its value. A room at the new clinic at 50, Park-place has been set apart and equipped for dealing with crippled children of all ages. A specially qualified nurse has been appointed to follow up such cases, to keep them in touch with the Prince of Wales's Hospital, and to administer massage, electricity, and postural treatment. Of the 286 cripples known to the department on August 31st, 1925, 93 were under the age of 5, 66 of whom were crippled by poliomyelitis and 12 by rickets. Of 188 cripples, aged from 5 to 16 years, 75 were the victims of poliomyelitis, 25 of tuberculosis, and 13 of rickets. The fact that there are only 5 known cases of rippling over the age of 16 shows that the registration for later ages is quite incomplete.

Dr. Picken thinks that the maternity and child welfare organisation would be improved if it were found administratively convenient to amalgamate the school medical nursing staff and the health visitors on lines similar to the amalgamation of the medical staff.

Sunderland.

Dr. Henry Renney reports that of 106 samples of milk examined for tubercle, 11 gave a positive result. In all cases the milks came from farms outside the borough, and in the majority of cases the veterinary surgeon on visiting found cows suffering from tuberculosis of the udder. The usual procedure adopted was to obtain an undertaking in writing from the farmer that he would not send milk from the infected cow into the borough. The antenatal centre at the maternity home has been given up, but the centrally situated antenatal centre has become "exceedingly popular" and an extension of its hours is necessary to meet the demand. Of the 115 cases of ophthalmia neonatorum notified, 94 were treated at the Eye Infirmary. Midwives attended 73·6 per cent. of the total births. There being no further need of a municipal midwife at the East End of the town, the office was terminated in December. There was only one case of puerperal fever notified during the year and no case occurred in the practice of a midwife. About 50 voluntary workers attend every week at the 11 infant welfare centres.

For the first time in 50 years there were no deaths from scarlet fever in the borough. The notifications of encephalitis lethargica, which numbered 4 in 1923, were 37 in 1924. There were only 2 deaths and no mention is made of steps taken to verify the diagnosis.

Bolton.

Dr. C. W. Paget Moffatt reports that the opening of the Moss-street baths and washhouses in October has conferred a great boon on the inhabitants. The building contains swimming baths for men and women, 18 slipper baths, and 24 washhouse stalls. The washhouses have so obviously supplied a very urgent want that it is hoped the same provision may be made before long in other quarters of the town. Dr. Moffatt presses the need for reasonably accessible playing fields for the younger members of the community. For non-pulmonary tuberculosis in children Bolton has a call on six beds at the Liverpool Children's Hospital, Heswall. This is not enough, and proposals are under consideration for a complete scheme for the treatment and care of cripples, including surgical tuberculosis.

Dr. Moffatt refers to the stationary position of the maternal and neonatal death-rates during the last 20 years. Thus for 1905–14 the neonatal rate was 41·7, and for 1915–24 it was 40·3. As regards prenatal work, Dr. Moffatt says it is essential that this work should now be extended by the establishment of a prenatal clinic in charge of a competent obstetrician. The Haslam Maternity Home admitted 220 cases during 1924. There were no maternal deaths during the year. In eight cases the baby was not entirely breast-fed while in the institution, in six cases because the milk was insufficient, in one case because the milk was not suitable, and in one case because the infant was premature. Six cases of insufficiency out of 220 cases is a high percentage. Notifications of encephalitis lethargica showed an increase. There were 40 cases with 17 deaths. All the notifying doctors were asked to supply particulars as to the present (i.e., May, 1925) condition. Of 26 survivors, 13 were reported to have recovered completely, six to be improving, and the remainder to be suffering from various forms of paralysis and mental and nervous symptoms. One case notified on April 5th committed suicide on Nov. 12th. In five cases certified to have died from this disease there had been no notification. The analyst's report shows that the percentage of cereal in shredded suet samples varied from 11 to 21. Ten per cent. of cereal is considered adequate to make a marketable product and any excess over this limit is added solely for extra profit.

Oldham.

Dr. James B. Wilkinson reports as the principal item in the year's work the Ministry's inquiry *re* the clearance of the Smethurst-street unsanitary area, which has been under consideration for over 14 years. The area covers 4·9 acres, contains 259 houses, and has a population of 1425 persons. The Coldhurst ward, in which the area is situated, had an infant mortality of 205 during 1924. There has been very little addition made to the house accommodation for the working classes during the year. The results from the treatment of a few marasmic and rickety babies at Westhulme Hospital have been so satisfactory that a small baby's hospital has been sanctioned by the Ministry of Health. Dr. Wilkinson draws attention to the fact that the only two wards which have a birth-rate of over 20 have low infantile mortality-rates. The damage done by ophthalmia neonatorum was one blinded baby, one with vision severely impaired, and one with vision slightly impaired. 13*s.* to 15*s.* per week for a single room containing a minimum amount of bedding and dilapidated furniture is a very usual charge, and shows that owing to the scarcity of houses "furnished rooms" can obtain just as high a rental as ever.

Bury.

Dr. G. Granville Buckley reports that the infant mortality-rate of 71 is by far the lowest ever recorded in the borough and compares with 101 for the year 1923. The Bury sanitary authority arrange with the Bury Infirmary for the treatment of complicated cases of labour and of non-pulmonary tuberculosis, and with the Manchester and Salford Hospital for Skin Diseases for patients suffering from tuberculosis of the skin. During 1924 eight cases of complicated labour and ten skin cases were treated under these arrangements. The tuberculosis dispensary, which was presented to the town by the Earl of Derby, is used jointly by the borough and the county council.

Wigan.

Dr. Henry Whitehead reports that there was a severe epidemic of measles during the latter part of the year. There were 78 deaths from this disease, making the unusually high death-rate of 0·85. In October two nurses from the Infectious Diseases Hospital were detailed to visit the cases and nurse the worst ones, and a third nurse began work in November. An up-to-date milk pasteurising plant has been established in the town, and in June the health committee decided to purchase pasteurised milk in bottles for the maternity and child welfare scheme and pasteurised milk in sealed kits for the supply of the borough hospitals. Dr. Whitehead records a small milk-borne outbreak of paratyphoid B. Eight cases were notified within ten days and were found to be supplied by two milkmen, who obtained their milk from the same farm outside the borough. A visit to the farm showed that the farmer had suffered from typhoid fever five years previously, and that his three daughters were out of health, one being convalescent and the other two ill with "influenza." Blood tests showed that all four were strongly positive to paratyphoid B. It seemed probable that the farmer was a carrier and had been the means of infecting his three daughters and the eight patients within the borough. Dr. Whitehead points out that pasteurisation would have prevented this outbreak. The scheme for the conversion of all privies and pail-closets to water-closets is going on very satisfactorily. Additional water-closets are also provided, when necessary, to enable each house to have its own convenience. Although more houses were built in 1924 than in 1923—namely, 74 compared with 23—the housing shortage is becoming more and more acute, and in consequence no definite progress can be made in dealing effectually with unsanitary areas or unsanitary dwellings.

Derby.

Dr. Albert E. Brindley reports an increase of encephalitis lethargica, there being 18 notifications and nine deaths. Small-pox became epidemic in April and continued throughout the year, 210 cases being notified with no deaths. The shortage of houses still prevents the demolition of unsanitary dwellings. From August, 1919, to the end of June, 1925, 940 new houses were built under the corporation scheme. At June 30th, 1925, 174 houses were in course of erection and 675 are to be begun in the near future. The natural increase of the population during the three years 1922–24 would absorb 750 houses. The mayor has put forward an urgent plea for the more rapid provision of houses, even if the construction is more or less of a temporary nature, and Dr. Brindley supports this view. Other needs of Derby are the increase of accommodation for patients and nurses at the isolation hospital, the extension of the dental service for expectant and nursing mothers, facilities for the dental treatment of tuberculous patients, and of patients in the isolation hospital, and the provision of an X ray installation.

West Bromwich.

Dr. R. Woolsey Stocks notes an increase in the attendances at infant welfare centres, but stresses the importance of extension of the work amongst toddlers and expectant mothers. He points out that the four maternal deaths from childbirth might have been prevented by antenatal attention, and that one can only hope to deal effectively with the high neonatal mortality by systematic antenatal examination. The number of mothers attending the antenatal clinic has increased to 150 from 51 in the previous years, and the number of mothers who submitted themselves for examination by the doctor was 94, as compared with 16 in the previous year. As the births numbered 1862 it will be seen that the antenatal work is on a very small scale. There is an improvement as regards the coöperation of the midwives, but there are still a number of midwives who never advise their prospective patients to come to the antenatal clinic, and "it is through the midwives that the greatest advance can be looked for in this work."

Nuneaton.

Dr. K. E. Tapper presents his third and last report before taking up his new duties at Bromley. He expresses his satisfaction that the infant mortality-rate has reached a figure below 60 for the first time, and in his report he indicates how further reduction may be obtained. Thus nearly half the infant deaths occurred in the first week, and 105 of the babies had been partially taken off the breast before the first visit of the health visitor. The total births numbered 971; antenatal sessions had only just been started at the end of the current year. The housing and living conditions of a portion of the population "are nothing less than deplorable." They are not wholly remediable by adequate housing conditions, as the "deplorable tenants" must be shown the error of their ways. A routine veterinary inspection of the milk cows in the borough has been begun. Thirty-five cases of small-pox were notified with no deaths. The deaths from encephalitis lethargica numbered five, the notifications 13. Dr. Tapper puts in a plea for a maternity home with accommodation for ailing babies. He sums up the housing needs of the borough as 500 new houses for 1925 and 300 for each of the next nine years. Thirty-four houses were erected under the municipal scheme for 1924.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED NOV. 28TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 105 (as under); scarlet fever, 2195; diphtheria, 1091; enteric fever, 54; pneumonia, 1531 (as compared with 1186 and 889 in previous weeks); puerperal fever, 52; cerebro-spinal fever, 7; acute poliomyelitis, 7; acute polio-encephalitis, 2; encephalitis lethargica, 41; dysentery, 2; ophthalmia neonatorum, 91. There were no cases of cholera, plague, or typhus fever notified during the week.

The cases of small-pox were reported from the following counties:—Derby, 11 (Derby C.B.); Durham, 71 (Gateshead C.B., 2; Blaydon, 26; Chester-le-Street, 1; Ryton, 1; Whickham, 4; Chester-le-Street R.D., 7; Easington R.D., 7; Houghton-le-Spring R.D., 7; Lanchester R.D., 8; Sunderland R.D., 8); Northumberland, 8 (Newcastle-upon-Tyne C.B., 7; Castle Ward R.D., 1); Nottingham, 5 (Nottingham C.B., 1; Hucknall, 2; Huthwaite, 1; Basford R.D., 1); Yorks, East Riding, 4 (Kingston-upon-Hull); Yorks, West Riding, 6 (Sheffield C.B., 5; Rawmarsh, 1).

Deaths.—In the aggregate of great towns, including London, there were 3 deaths from enteric fever (1 in London); 50 from measles, 11 from scarlet fever, 40 from whooping-cough, 54 from diphtheria, and 73 from influenza. In London itself there were 15 deaths from diphtheria and 25 deaths of infants under 2 years of age from diarrhœa and enteritis.

VETERINARY RESEARCH.—The Council of the Royal College of Veterinary Surgeons has awarded the Steel Medal for Veterinary Research to Prof. S. H. Gaiger, F.R.C.V.S. Under the John Henry Steel Trust the Council of R.C.V.S. has power to award a medal once in three years as a reward for scientific or literary work of merit connected with the veterinary profession. Prof. Gaiger was until recently director of research in the Animal Diseases Research Association, Glasgow. He has done good work in connexion with several sheep diseases and has carried out some investigations into "grass disease" of horses. He has recently been appointed to the "William Prescott" Chair of the Care of Animals—Causation and Prevention of Disease, in the University of Liverpool.

The Services.

ROYAL ARMY MEDICAL CORPS.

Capt. G. O. F. Alley relinquishes the temp. rank of Maj. on ceasing to be empld. as a Dept. Asst. Dir. of Hygiene and Pathology.

Capt. F. C. Tibbs is granted the temp. rank of Maj. whilst empld. as a Dep. Asst. Dir. of Hygiene and Pathology.

Capt. H. Jacques to be Temp. Capt., and temporarily relinquishes the rank of Capt.

Capt. W. O. Tobias retires, receiving a gratuity.

TERRITORIAL ARMY.

Capt. J. A. Stenhouse to be Maj. (Prov.).

Lt. N. Braithwaite to be Capt., and Lt. J. C. MacKay to be Capt. (Prov.).

Lt. H. Miller (late R.A., T.A.), to be Lt.

ROYAL AIR FORCE.

Flight Lt. W. F. Wilson is promoted to the rank of Squadron Leader.

MEDICAL SERVICES IN INDIA.

The King has approved the relinquishment of their temporary commissions by Capt. Ramchander Kaushash and Lt. Shanker Ramchandra Joglekar.

The undermentioned, the relinquishment of whose temporary commission has been notified, is granted the rank of Capt: Nur Ahmed Quraishi, late temp. Capt.

Maj.-Gen. D. J. Collins, C.B., C.M.G., who has been officiating for Maj.-Gen. Robinson as D.M.S. India, has resumed his permanent appointment of D.D.M.S. Southern Command. Lt.-Col. A. K. Lauddie has handed over the charge of the District Jail, Ferozepore, to Dr. Jamna Das. Lt.-Col. H. W. Pierpoint, late residency surgeon, Bushire, has been appointed Superintendent of the X Ray Institute at Dehra Dun. Lt.-Col. G. McPherson has been appointed Civil Surgeon, Ahmednagar. Maj. G. Holroyd, on return from leave, is appointed Superintendent, Central Prison, Bareilly. Dr. A. Souza, Assistant Director of Public Health, United Provinces, has been deputed to Japan to participate in the tour of Health Officers in Japan organised by the League of Nations. Capt. G. D. Mahoutra officiates as O.C., Indian Station Hospital, and as Officer in Charge, Brigade Laboratory, Allahabad, during the absence on leave of Capt. M. L. Dhawan. Maj. J. L. Sen is appointed Civil Surgeon, Cachar, Assam. Maj.-Gen. R. Heard, C.I.E., ia appointed President of the Bengal Council of Medical Registration, vice Col. R. P. Wilson resigned. Maj. C. H. P. Allen has been appointed Civil Surgeon, Sadiya. Dr. P. Gupta has been appointed Assistant Director of Public Health, Assam. Lt.-Col. J. H. Murray has been confirmed as I.G. of Prisons, Bombay Presidency, vice Lt.-Col. F. O. M. Mell retired. He has proceeded on leave, and Maj. E. E. Doyle, D.S.O., Superintendent, Central Prison, Yerrowda, officiates for him. Maj. W. E. Rees Williams, D.A.D.M.S., Southern Command, proceeds on a year's leave; Maj. A. C. Wood acts for him. Rao Bahadur Dr. P. V. Shikhare, Bombay Medical Service, who represented the Bombay Government at the International Congress on Child Welfare in Switzerland last July, has returned to India and taken over the appointment of Civil Surgeon of Thana. Col. H. Ainsworth, Inspector-General of Civil Hospitals, Bihar and Orissa, has returned from leave and resumed his substantive appointment.

Jail Reform.—A conference of I.M.S. officers, acting as I.G.'s of Jail, was held in Madras last month to consider jail reforms in India.

DEATHS IN THE SERVICES.

Lt.-Col. Robert Evans Stuart Davis, I.M.S. (retd.), who died on Nov. 25th in Belfast, received his first commission in the Indian Medical Service in 1882. He served with the Burmese Expedition 1886–87 (mentioned in despatches, medal with clasp), and was for some time a civil surgeon at Rangoon. He retired in 1910.

Lt.-Col. James Comeford Sullivan Green, late R.A.M.C., died at Airhill, Glanworth, Co. Cork, at the age of 64 on Dec. 1st. He graduated in medicine and surgery at Dublin University in 1883. Having previously served in the army as surgeon, he was appointed Major, R.A.M.C., in 1897. He accompanied the expedition to Manipur in 1891 (medal with clasp), served in Burma during the two following years, and afterwards took part in the operations of the Irrawaddy Column. In the South African War, 1899–1902, he took part in the actions at Elandslaagte, Reitfontein, and Lombards Kop. He was present at the defence of Ladysmith and served in the operations in the Transvaal, Orange River Colony, and Cape Colony (Queen's medal with five clasps and King's medal with two clasps).

Correspondence.

"Audi alteram partem."

EPSOM COLLEGE:

ROYAL MEDICAL FOUNDATION.

To the Editor of THE LANCET.

SIR,—Last Christmas I humbly approached your readers on a note of entreaty; this Christmas I approach them again on a note of gratitude, not unmixed with a hope of further favours to come. We have won the support of many additional annual subscribers but, like Oliver, I am still handing up my plate for more. A most gratifying response has come from the Panel Committees throughout the country; without any question of a *quid pro quo* they have just done what they could, and certainly one boy owed his success in the election last June to their activities. We are deeply indebted also to our many honorary local secretaries, some of whom have sent us most substantial returns, and to the great medical institutions—to the British Medical Association and its journal, to THE LANCET, and to the Medical Insurance Agency. So sedulously did the Pathological Society, under the leadership of Profs. Dean and Boycott, canvass new subscribers that they secured at the first attempt a high place on the list of successful candidates for the son of a recently deceased pathologist. The increased subscription list has enabled us to do many things a little better, and to give materially greater advantages to our 50 foundation scholars. In the school department substantial improvements in the salaries of some of our masters have been made, a very important step, for good teaching is a basic requirement.

In the matter of legacies and benefactions we have been very fortunate too; it is on these that we depend almost entirely for the immediate provision of the more costly improvements that we effect. The rebuilt chapel—a war memorial mainly provided by old Epsomians—was dedicated last February; a well-known old Epsomian has beautified it with a gift of handsome silver-plated candlesticks, vases, and an alms-dish, and has also been instrumental in securing a contribution of £1000, which by his wish is being spent on Gothic oak panelling for the chapel. Four generous donors contributed a total sum of £1300, which has permitted a complete transformation of the library and a good equipment of new books. We have promises of the bequest of parts of two valuable libraries, but let me hasten to say that we welcome suitable books from the living as well as from the dead. If each medical man were to give one well-bound book, what a library we should have!

Carefully husbanded legacies have enabled us to lay the foundation-stone of a new chemistry block by the hand of our President, Lord Rosebery, and we intend to open it next midsummer on Founder's Day; this is costing rather more than £10,000. At the same time we are taking in hand the concentration of a scattered, wasteful, and nearly worn out heating installation at a cost of some £5000, and we can see our way also to much-needed additions to the accommodation for washing and drying for the boys in the lower school—another £2000 or more. There we reach the bottom of our pocket until kind friends of the College can give or influence the giving of legacies or benefactions for other objects of which I venture to name a few.

The provision of a new infirmary would be a priceless boon to the school. The present infirmary is not constructed according to the requirements of modern medicine and nursing, and is uneconomical to run. Our medical officer has plans for a model school infirmary which would cost from £15,000 to £20,000. The vacated infirmary would give accommodation to 45 more boys from our waiting-list which now totals nearly 500, and this addition to the total numbers would make the school a much more economical unit in many directions. What a chance for a wealthy patient as a thank-offering for life or limb! and for the Council to inscribe his name on it in perpetuity! More houses for married masters are a standing need, as also is an entrance lodge adjoining the College quadrangle. Some sportsman may be tempted to build a sports pavilion or to undertake the much-needed levelling of the lower school playing fields.

But in dangling these grandiose proposals before the eyes of potential benefactors we must not lose sight of our humble daily needs, whereby we educate and maintain our foundation scholars free of cost and distribute also many pensions; if funds were available we should like to increase these pensions, owing to the present high cost of living. One guinea annually, or a single donation of ten guineas, makes a governor and gives ten votes at each election in June of foundationers and pensioners, and each additional guinea gives ten votes more. We already relieve much distress in the profession; will you help us to relieve much more?

Subscriptions and donations may be sent to the Secretary, Epsom College Office, 49, Bedford-square, London, W.C. 1, who will be glad to give any information and welcomes personal visits at any time.

I am, Sir, yours faithfully,

RAYMOND CRAWFURD,

Chairman of the Council of Epsom College.

December, 1925.

TELLING THE TRUTH.

To the Editor of THE LANCET.

SIR,—In his letter of Nov. 28th on "Telling the Truth," "Croix Rouge" fails to distinguish between a *broad* and a *pure* mental reservation. He is also mistaken in the matter of Jesuit teaching. According to all moralists a lie, falsehood, or untruth is the act of *speaking against one's mind*. To borrow from a friend, saying: "I will pay you back," but adding in your mind "if I have any money," is to use words in a limited meaning without giving any outward clue to the limitation. This the Jesuits do not call diplomacy, but pure mental reservation, and that, to quote Father Joseph Rickaby, S.J. "is in nothing different from a lie, and is wrong as a lie is always wrong."[1] By that definition the dealer in antique furniture who says, "I guarantee that this is old," laying his hand on the genuine portion of a faked chair, is merely a skilled liar.

A *broad* mental reservation is different. Here the spoken words correspond to the thought in the mind —*secrets apart*—and therefore no lie is told. The reader may ask how it can be anything but *speech against the mind* when the mind thinks *yes* and the tongue says *no*. The answer is that in those cases where broad reservation is permissible the thought in the mind is "secrets apart—no," and that the word spoken is not to be taken as the whole locution.

> "The word is an *annotated text; nay*, in the body of the page, with *secrets apart* inscribed in the margin. The adequate utterance is the whole page, text and gloss together; that speech answers to the thought in the speaker's mind; therefore it is no lie. The essential requisite is that the gloss, *secrets apart*, be not written in the speaker's private mind, but be outwardly and publicly manifest in the matter spoken of, which must be one that clearly admits of secrets, and in the circumstances of the speaker, who is driven into a corner, and obliged to answer something, and yet cannot by any prudent man be expected to answer out of the fullness of all the knowledge that he may possibly possess."[2]

The next point to seize is that—

> "broad mental reservation is permissible only as a last resort, when no other means are available for the preservation of some secret which one has a duty to others, or grave reason of one's own, to keep."

What, then, are those secrets? The Jesuits teach that there are four kinds of secrets. *Natural* secrets are all a man's own private history, and all that he learns by observation of the similar private history of his neighbour. Next come secrets of *promise*, as when a man has found out something about his neighbour and the neighbour gets him to promise not to publish it. These two kinds of secrets must be revealed on the demand of an authority having the right of inquiry into matters touching on the secret. In another category is the secret of *trust*, confided to a lawyer or to a physician in the practice of his profession. The secret of trust is privileged. It is to be defended by silence, and where that be ineffective by broad reservation. For that reason I would not hesitate to tell "the pretty," or, may I add, the plain "wife of a faithless husband" that he had become infected through drinking out of a glass. Indeed, if Venus followed Bacchus the statement would be an excellent example of broad reservation. Last are the *secrets of confession*, which are absolutely inviolable, and in the Jesuit Church at Farm-street is the statue of a man who was martyred in this cause. The Jesuit died under torture; the seal of confession was unbroken.—I am, Sir, yours faithfully,

HALLIDAY SUTHERLAND.

Wimpole-street, W., Nov. 30th, 1925.

To the Editor of THE LANCET.

SIR,—The Psalmist said in his haste, "All men are liars." "Croix Rouge," in your issue of Nov. 28th, deliberately admits the truth of the statement. There appear to be exceptions, but the statement is, in this day, so nearly true that I would not trouble to controvert it. He, however, unlike the Psalmist, seems to regard this state of affairs as justifiable. There I emphatically disagree with him. To quote and translate a passage from Homer, "He is hateful to me as the Gates of Hades who conceals one thing in his mind and says another."

Every discreet man will, of course, very frequently conceal what is in his mind, but he need not, and should not, say another thing with intent to deceive. A lie is a false statement deliberately made with intent to deceive the hearer. Polite, or "white" lies as they are called, are merely conventional methods of veiling our actual feelings which often ought to be concealed. Lies told from motives of self-interest are in a totally different category and are sometimes even criminal. There is, no doubt, something to be said in favour of the kind of lies to which "Croix Rouge" seems especially to refer as being permissible. Let us take an example. A young woman consults a doctor about a tumour in her breast which he finds to be a cancer. To tell her that it is a cancer will do no good and will probably do considerable harm. He should, therefore, not tell her the nature of it if he can avoid it, but should, for his own protection, be provided with evidence to prove that he has made a diagnosis of cancer. Unfortunately, the patient, ignoring the fact that in these cases "ignorance is bliss," may insist on a definite answer to the question whether it is or is not a cancer. According to "Croix Rouge" he should say it is not a cancer. He then has to advise complete removal, and will have to tell more lies to try to persuade the patient. In order to succeed he may think it advisable to tell the truth to responsible relatives. He is in either case exposed to grave disaster. The patient, on the strength of his positive assurance, may absolutely refuse operation, and if he weakly yields he will later on be threatened with an action for damages for negligently causing the patient to lose the chance of cure. If he bravely admits that he has lied, or if the truth confidentially communicated to others has leaked out (as often happens), his patient, in a condition of mixed fury and despair, will probably tell him that as he has lied to her she can never trust him again and will change her medical adviser. He will then recognise that though the "bread of deceit is pleasant to a man it is afterwards as gravel in his mouth." It must also be remembered that although lies are sometimes undetected, the most skilful liar will soon have some of his lies exposed; and what value can be attached to the statements of a man when we know that he will lie whenever he thinks it expedient to do so. In another connexion, what scientific value can be attached to the results of the researches of the ablest man if he is known to be a liar? It is a matter of good taste to say of the dead "nil nisi bonum," but it is a matter of honour and duty to say to the living "nil nisi verum."

[2] Loc. cit., p. 234.

I am, Sir, yours faithfully,
Nov. 30th, 1925. HUGH WOODS.

To the Editor of THE LANCET.

SIR,—*Aliquando bonus dormitat Homerus.* Your sub-editor—the editor himself is unthinkable—must have been acting Homer to pass the poison gas carried by "Croix Rouge." There are in every large profession blacklegs and outsiders whose morality and methods are beneath contempt.

I am, Sir, yours faithfully,
Dec. 7th, 1925. VERITAS.

RHEUMATISM: WANTED, A NEW NOMENCLATURE.

To the Editor of THE LANCET.

SIR,—Your issue of Dec. 5th contains a report of the joint meeting of the International Society of Medical Hydrology and the Section of Balneology held at the Royal Society of Medicine on Nov. 27th. The lay press reported this meeting very fully. A survey of these latter reports and conversation with many intelligent laymen brings out the interesting fact that what chiefly interested the public in this discussion was the impression that rheumatism not only cripples thousands of people in every European country, but is further responsible for an enormous death-rate owing to the frequency with which it causes heart disease.

The distinction between rheumatic fever, a disease of children which never causes chronic joint changes and frequently provokes serious cardiac lesions, and rheumatoid arthritis, a disease of adults which tends to cause chronic joint changes and very seldom affects the heart at all, would appear to be too fundamental and established to require emphasis to-day. The importance of each of these diseases is so great that confusion concerning them is deplorable, but it is no exaggeration to say that a discussion of one or the other, whether at a meeting or in the columns of a medical journal, never takes place without the two being jumbled together in almost hopeless disorder. Is not this essentially a case where chairmen and editors should exercise their powers of veto in the hope of making discussion fruitful?

If the unanimity of our text-books and our teaching is not sufficient to make the matter clear, it becomes open to question whether we should not adopt a new nomenclature. "Rheumatic fever" and "acute rheumatism" are unquestionably the terms responsible for the confusion. It is perhaps time that a new name were adopted for this disease, preferably one which would incorporate a conception of its serious cardiac effects and cease to emphasise its quite trivial articular manifestations.

I am, Sir, yours faithfully,
London, Dec. 5th, 1925. T. IZOD BENNETT.

"A DISCLAIMER."

To the Editor of THE LANCET.

SIR,—Is there any real necessity for the publication of disclaimers such as that which appears in THE LANCET of Dec. 5th, p. 1198? Is every medical man who delivers a public lecture to be prohibited from allowing his name to be announced to his prospective audience? Surely this is a *reductio ad absurdum.* I write this letter for information, not for advertisement!—I am, Sir, yours faithfully,

LEONARD F. BROWNE.
Harley-street, W., Dec. 7th, 1925.

LANCASHIRE AND THE SPAHLINGER TREATMENT.

To the Editor of THE LANCET.

SIR,—On p. 1203 of your issue of Dec. 5th one reads the following: "Dr. Thomas Watts, M.P. (Withington), said that he and his colleagues who went to Geneva traced a definite 80 per cent. absolute recoveries, which was very different from 14 per 1000 in this country. . ." One would like to know the basis of his statement that only 1·4 per cent. of recoveries are to be expected from sanatorium treatment. It is obviously a ludicrous inaccuracy. Is it, I wonder, the printer's or the speaker's error?

I am, Sir, yours faithfully,
F. G. CHANDLER, M.D., F.R.C.P.
Park-square West, N.W., Dec. 5th, 1925.

⁂ Our report was published as it was received and the figures given by the speaker will be generally considered to require explanation.—ED. L.

THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND ITS MEMBERS.

To the Editor of THE LANCET.

SIR,—The request on the part of the Members of the College (Conjoint Diplomates) for an improved status by the grant of a voice in the affairs of their College is only natural. The Member comes in contact with disease in its early stages. Upon his outlook, discrimination, and powers of diagnosis depends the quantum of benefit received by the patient. Early diagnosis is of priceless benefit to the public. It can be truthfully said that to be a good family doctor is as difficult, if not more so, than to be a specialist. Is the benefit of his skill likely to be developed by men who have an inferior status? An improved status would stimulate the Member to greater efforts for the common weal. The gulf between the general practitioner and specialist would be lessened, which, I submit, would be in the interest of common humanity.—I am, Sir, yours faithfully,

F. W. COLLINGWOOD.
Royal Colonial Institute, Northumberland-avenue,
London, Dec. 8th, 1925.

DIABETES AND OPERATION.

To the Editor of THE LANCET.

SIR,—In his article on Diabetes and Operation, which appears in THE LANCET of Dec. 5th, Dr. O. Leyton draws attention to the fact that a general anæsthetic usually makes the diabetic condition much more grave and states that, in his experience, it is extremely rare for a general anæsthetic, other perhaps than nitrous oxide and oxygen, not to lead to a definite deterioration of the carbohydrate metabolism in cases of diabetes mellitus. We have investigated this question and find that if appropriate treatment be carried out before, during, and after operation, as described by us in THE LANCET (1924, ii., 647), no such deterioration will occur. In only one of our cases was there evidence of the diabetic condition becoming more grave, although ether was invariably used as an anæsthetic. The other cases are now free from glycosuria. Since this date we have advised on the question of operation in many other diabetics, with results that have been uniformly good.

We are, Sir, yours faithfully,
H. S. PEMBERTON.
Liverpool, Dec. 8th, 1925. L. CUNNINGHAM.

HOSPITAL CONTRIBUTIONS FROM SHEFFIELD CITY COUNCIL.—Under the Public Health Act, 1925, which came into operation two months ago, the Sheffield City Council was empowered to make contributions to the Hospitals "Penny-in-the-Pound" scheme. It has now decided to give one-third of the amount contributed by 5000 of its employees, and it is believed that the total will reach about £1500 per annum.

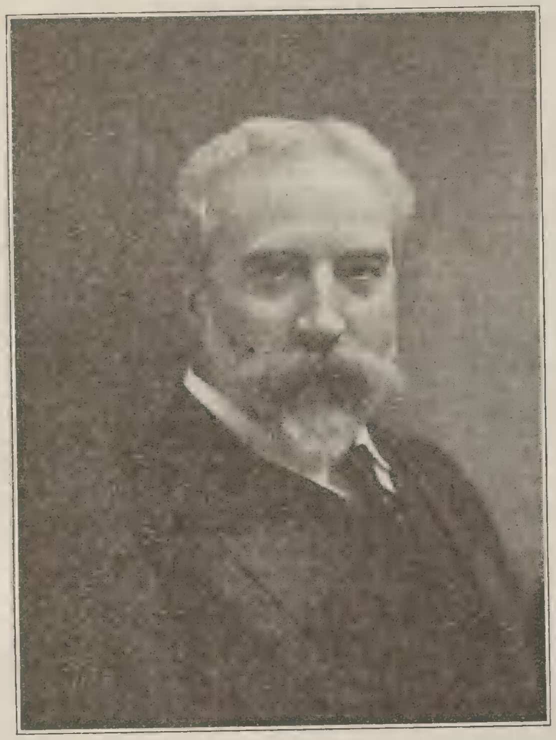
Obituary.

SIR JOHN MACALISTER, F.S.A.,

LATE SECRETARY AND LIBRARIAN OF THE ROYAL SOCIETY OF MEDICINE.

WE have announced already the death of Sir John MacAlister, which occurred on Tuesday, Dec. 1st, at his residence in Finchley-road, in the 70th year of his age. The sad event could not have been an unexpected one for any of his numerous friends and acquaintances, while the medical profession at large were prepared for this sequel to his recent resignation, owing to seriously failing health, of his official position at the Royal Society of Medicine.

John Young Walker MacAlister was born in 1856 of an ancient Scottish family. He was educated at the High School, Liverpool, and later was for three years a medical student in the University of Edinburgh. Shortly, however, before completing the curriculum his health broke down, and he was advised to choose a profession of a less exacting physical nature, with the result that he became sub-librarian of the Liverpool Library. It soon became clear that he had both the love of order and the love of books necessary to be a valuable librarian, and in 1880 he was appointed chief librarian to the Leeds Library, where he had a full opportunity for displaying his exceptional abilities; for new buildings were in the course of erection at Leeds, and MacAlister's designs were followed in regard to a considerable part of the internal structure. There was already at Leeds a large collection of books, and these were catalogued in accordance with the new librarian's scheme of classification, which was afterwards adopted under his management in the library of the Yorkshire College, the constituent college of the Victoria University, which formed the origin of the University of Leeds. With this record it is not surprising that in 1887 the National Liberal Club in London should have nominated him as the librarian of the Gladstone Library of the Club, but his tenure of the position was a brief one. It gave him the opportunity of personally meeting Gladstone, and hearing from the great statesman's own mouth the ideas on library arrangement which personally appealed to him; but within a few months the post of librarian and secretary at the Royal Medical and Chirurgical Society fell vacant, and MacAlister, throughout his life deeply interested in all medical activities, became a successful applicant for the vacancy.



SIR JOHN MACALISTER.

From this time forward MacAlister's life was lived in association with that society and with the great body, the Royal Society of Medicine, into which it later developed, and in the Transactions of the Royal Society of Medicine there will be found from his own pen a modest but clear account of the prominent phases in a career of eager and successful activity. The Royal Medical and Chirurgical Society had its home at 53, Berners-street, when MacAlister became its executive officer, the rent was £14 a year, the lease had 13 years to run, and no preparation had been made either to meet the fifty-fold rent which with perfect reason would be demanded shortly, while there had been no sinking fund provided for dilapidations. The number of Fellows was about 800, and, to quote MacAlister's own words, "the subscriptions barely made ends meet, and a new chimney-pot caused a deficit in the annual accounts." When, after looking closely into the situation, he spoke of it to prominent members of the Society, no one seemed very interested; one of those to whom he went for advice suggested doubling the subscriptions, while another said that if that was done half the members would resign, and the new official was left more or less to find a way to salvation for persons apparently resigned to impending disruption. Many may remember what happened. MacAlister conceived the idea that the Society might become the owners of premises of such a character that portions could be let off, leaving substantial premises for the Society at no great annual cost. A suitable house, however, had to be obtained, while a capital sum would be necessary before it would be possible to enter into possession of such a building. MacAlister found a large house in Hanover-square, which had stood empty for some years, and the sum of money demanded for it seemed to him moderate. He immediately placed the whole scheme before Sir Andrew Clark, the President of the Society at the time, and with characteristic energy Clark, having approved the idea generally, called for details, asked pertinent questions, promised a decision at a meeting to be held early the following morning, discussed the plans at the meeting, and headed a proposed debenture list with a cheque for £10,000. The prosperous growth of the Royal Medical and Chirurgical Society, which immediately followed on the move to 20, Hanover-square, would have probably filled to satisfaction the days of most secretaries. But actually before the house was rehabilitated so as to accommodate the lodgers, whose pleasant duty it would be to pay the rent, MacAlister, with Sir Andrew Clark as his backer, produced a scheme for the amalgamation of the medical societies of the metropolis, whereby all the strength and solidarity of the combination would be ensured for every body which joined, while economy would be achieved in personnel, and overlapping activities could be avoided. Whether the medical profession or the various metropolitan societies were in these early days prepared for the scheme is doubtful, but, anyhow, it fell into abeyance with the premature death of Sir Andrew Clark. The delay, however, was not long, for in 1905 MacAlister submitted to Sir Richard Douglas Powell, then President of the Royal Medical and Chirurgical Society, a revised scheme for amalgamation which had been ventilated 12 years previously. This scheme received the approval of a large group of leaders of the medical profession within and without the metropolis, but the interests involved were numerous and not always identical, and the negotiations extended over two years or more. During this time, in the first place, membership of the Royal Medical and Chirurgical Society gained in numbers until it became obvious that a new house would have to be obtained, while, in the second place, the idea of fusion had become familiarised to many of the bodies concerned by the fact that a considerable group of them were already the sub-tenants of the Royal Medical and Chirurgical Society. MacAlister was the mainspring of all the business, he initiated the negotiations, carried them on, and suggested the conditions by which they should be determined, and when a suitable site for a Royal Society of Medicine was found at the corner of Wimpole-street and Henrietta-street he performed financial miracles in getting money with which to buy and finding arguments for securing good terms.

The following tribute from Sir StClair Thomson, the President of the Royal Society of Medicine, continues the story of MacAlister's connexion with the Society, showing what an astonishing change in the academic life of the medical profession in the metropolis has been effected through MacAlister's organising talents. Sir StClair Thomson writes :—

"It was chiefly through his organising talents that the Medical and Chirurgical Society moved to a larger house in Hanover-square, and there amalgamated itself with 18 other distinct medical societies of London into the now flourishing Royal Society of Medicine. MacAlister's indomitable energy was the chief factor in erecting the handsome home for this great amalgamation at the corner of Wimpole-street and Henrietta-street. He who had commenced as librarian to a society of 745 Fellows, with an income of about £1600 per annum, lived long enough to be secretary of a society of 4000 Fellows, with an income of £20,000 a year, and possessing, among other valuables, the largest medical library in the British Empire.

"This fusion of 18 separate and independent societies was really a Herculean work, if it is remembered how many conflicting interests and jealousies had to be overcome. Many efforts at the task had failed since the foundation of the original Medical and Chirurgical Society in 1805. It was nearly successful in the time of Sir Andrew Clark, but the untimely death of that great physician arrested progress until it was finally accomplished in the year 1907, when Sir William Church, ex-President of the Royal College of Physicians, became the first President of the Royal Society of Medicine. This great achievement was doubtless accomplished because MacAlister was a man with imagination, was absolutely devoid of selfishness, and was single-hearted in his devotion to a great idea. Fortunately he was a man endowed with a serene and equable temperament which allowed his Celtic imagination to be controlled by the more rational spirit of his Southern friends. If any project of his was occasionally turned down as visionary or impracticable, he was neither resentful nor cross about it.

"His handsome presence will not easily be forgotten. He was twice threatened with tubercle. He suffered from other troubles, for the relief of which he was ever grateful to his old friend, Sir Arbuthnot Lane. But he never looked the invalid. Broad-shouldered and erect, with his handsome head of hair and curling beard, with the refined straight nose and the high cheekbones of the Celt, his one grey and his other blue eye added an increased charm, while his clear diction and low, musical voice had an attractive and caressing effect. In his prime there was something about him suggestive of the Viking type, with which much of the Highland strain on the coasts of Scotland is mingled. This same Celtic strain gave him a love of hospitality, a sociability, a courtesy, a facility of approach, and a pliability which is sometimes wanting in the Lowlander. Possibly it also accounted for a certain respect for the ceremonial and bravura of public affairs, and for the simplicity and frugality of his private life. He was known to and beloved by successive generations of medical men. There is hardly a consultant or specialist in London to whom he was not a friend and a helper. Outside the profession he was ready to join in any undertaking of public interest, and particularly those concerned with books and libraries. His catholic tastes were shown by his membership of the Athenæum, Garrick, and Bath Clubs, and his life-membership of the Savage Club. He was, in Dr. Johnson's true meaning of the word, 'a very clubbable man.'

"The Council intend to hang his portrait in the entrance hall. Fellows will recognise in this fine portrait that the artist has not omitted to indicate, by the surroundings, his love of books and libraries, and his great share in the erection of the Society's house. The cigar in his hand indicates his devotion to 'my lady Nicotine' and no sweeter incense could be burnt before his picture than the tobacco smoke which will in future curl up round it during the tea hour. It is one of the curious, though not uncommon, coincidences of our great country that MacAlister and the last President to be associated with him both came from small neighbouring villages on the shores of Loch Fyne, and yet it was not in Argyllshire, but in Berners-street that they met for the first time.

"When I saw him shortly before he died he told me he had not smoked for two days, and then, as Mistress Quickly said, 'I knew there was but one way.' He was able still to take great interest in the most recent doings of the Society, and gave voice to his well-known chuckle when I told him that the annual dinner had been so managed that it had left us with a profit instead of the usual deficit. He had neither distress nor pain, for the devoted attentions of his family, his friends, and his faithful attendant, Dr. Moreland McCrea, had smoothed the last stormy passage. His only complaint and his last words were: 'I am only tired—very tired—always tired.'

"His best and most enduring memorial will be the house of the Society he served so long and faithfully. As was said of Sir Christopher Wren : *Si monumentum requiris, circumspice.* If those interested care to look up 'Who's Who' they will see that he has quizzingly recorded that his chief recreation was 'sleeping'! After life's fitful fever our friend sleeps well."

Outside the Royal Society of Medicine MacAlister was well known as a librarian. He was instrumental in founding the library which is now the organ of the Bibliographical Society. Nearly 40 years ago he became honorary secretary of the Library Association, and he played a prominent part in securing the passage of the Act which in 1892 regularised the conduct of public libraries. During the war MacAlister acted as secretary of one of the War Office committees, and in that capacity organised a service to afford surgical and medical assistance in the casualties of the metropolis arising out of air raids. In 1920 he was knighted, and his numerous friends testified their pleasure at the State recognition of his services by making him the guest at a very large and successful banquet, and presenting him with a testimonial.

Sir John MacAlister married Elizabeth, daughter of George Batley, of Blackhall, Edinburgh, by whom he had two sons. To them and to Lady MacAlister we tender our sympathy in the loss which they have sustained.

RICHARD JOCELYN SWAN, M.R.C.S. ENG., L.S.A., L.M. DUB.

THE death took place at Wallington on Dec. 7th of Dr. Richard Jocelyn Swan at the age of 76 years. He was the second son of the late Dr. John Wright Swan and was born in 1849 at Ballyragget, Co. Kilkenny. He studied medicine at Steevens' Hospital, Dublin, where he was awarded the Cusack Surgical Clinical Prize in 1868. After qualification at the Royal College of Surgeons of England, he was appointed assistant obstetric physician to Steevens' Hospital, relinquishing this post to take up general practice first in Northleach, Gloucestershire, later in Lincolnshire, and from 1885 in South London. For upwards of 25 years Dr. Jocelyn Swan acted as consulting surgeon to the tramways staff of the London County Council. He took a keen interest in the affairs of the Irish Medical Schools and Graduates Association, of which he was treasurer for 20 years and president in 1913. He also took an active interest in the Volunteer Army, both in the Lincolnshire Regiment and in the 1st Surrey Rifles, and during the Great War was on the active staff of the Belmont Hospital, Sutton.

Dr. Jocelyn Swan leaves a widow, the daughter of Dr. Robert Harper, of Holbeach, Lincolnshire, by whom he had two sons and one daughter.

THE LATE SIR ROBERT CHARLES BROWN.

THE career of Sir Robert Charles Brown, of Preston, was briefly set out in THE LANCET of Nov. 28th (p. 1142). Dr. F. W. Collinson, his colleague on the staff of the Preston Royal Infirmary, writes to point out Sir Charles Brown's life-long services to that institution. He assisted in the collection of money for the erection of the original building. He was on the staff from the time the infirmary was opened in 1870 to his death, first as house-surgeon, then as honorary physician, and, for a number of years, as consulting physician. After inspecting the best in use elsewhere, he built, entirely at his own expense, an up-to-date operating theatre with all the necessary appurtenances. He provided isolation wards, conservatories, and many other things for the comfort and welfare of the patients. When X rays were first introduced, he defrayed the cost of an outfit, which was the best of its kind at the time. In all, his gifts to the infirmary amounted to more than £10,000. He was, adds Dr. Collinson, a man of simple tastes with no desire to spend money upon himself, and frequently denying himself that he might have more to bestow on others. In his later years he often spoke of having "found the value of money now that he was giving it away."

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 2ND.

Pharmacists in the Army.

Mr. ALFRED WILLIAMS asked the Secretary of State for War whether he could state the number of pharmacists who had specially enlisted as such during the years 1922, 1923, and 1924; and what rank was accorded to pharmacists on enlistment.—Sir L. WORTHINGTON-EVANS replied: No pharmacists were enlisted in the regular army during the years in question, but five were enlisted in the Royal Army Medical Corps (Supplementary Reserve) during 1924. All pharmacists are enlisted in the rank of private.

Inoculation of Soldiers.

Mr. COMPTON asked the Secretary of State for War on what grounds it was made compulsory for recruits on enlistment to be vaccinated on one arm and inoculated on the other at the same time and for a second inoculation to be performed within ten days.—Sir L. WORTHINGTON-EVANS replied: The hon. Member is under a misapprehension. Soldiers are not inoculated until they are about to proceed on foreign service.

Vaccine Lymph.

Mr. GROVES asked the Minister of Health whether oil of cloves was used in the preparation of vaccine lymph.—Mr. N. CHAMBERLAIN replied: The answer is in the affirmative.

THURSDAY, DEC. 3RD.

Closing of Pensions Hospitals.

Colonel ENGLAND asked the Minister of Pensions how many Ministry of Pensions hospitals had been closed within the last 12 months; and how many ex-Service men requiring treatment were awaiting admission to the existing hospitals at the present time.—Major G. C. TRYON replied: Seven hospitals have been closed within the past 12 months. The average number of men awaiting admission to hospital is slightly over 400 at any one time. This compares with an average weekly number of 480 admissions to and 470 discharges from the hospitals. There is an average floating balance of 460 beds always available.

Orpington Hospital.

Captain BOWYER asked the Minister of Pensions whether, in view of complaints regarding the treatment of neurasthenic ex-Service men at Orpington and at other hospitals, he would definitely state that no economy had been, was being, or would be, practised at the expense of these ex-Service men.—Major G. C. TRYON replied: I can unhesitatingly give my hon. and gallant friend the most complete assurance to this effect.

Pensions Ministry Hospitals.

Mr. DENNISON asked the Minister of Pensions how many institutions there were under the control of the Ministry for the treatment of pensioners and where they were situated; and what was the charge made against pensioners' allowances at the institutions under his control for the treatment of the mentally afflicted.—Major G. C. TRYON replied: There are 23 institutions under the entire control of the Ministry, and three where that control is partial only. With regard to the latter part of the question, the charge, if any, made against a pension or allowance during treatment, either in a public institution or one controlled by the Ministry, is determined by the provisions of Article 6 of the Royal Warrant and of the Lunacy Acts. In those cases where any charge is made the maximum is 37*s.* 6*d.* a week. The following are the institutions referred to: Bellahouston, Glasgow; Craigleith, Edinburgh; Edenhall, Musselburgh; Castle Leazes, Newcastle-on-Tyne; Becketts Park, Leeds; Kirkburton, Huddersfield; Grangethorpe, Manchester; Mossley Hill, Liverpool; Maghull, Liverpool; Chepstow, Wales; Rookwood, Cardiff; Watson Home, Birmingham; Harrowby, Grantham; Saltash, Cornwall; Coombe Park, Bath; Fernbank, Roehampton; Latchmere House, Richmond; Ewell, Surrey; Orpington, Kent; Rotherfield Court, Henley-on-Thames; The Spring, Hanwell; Leopardstown Park, Dublin; Blackrock, Dublin; and (under partial control) Highbury, Birmingham; Roehampton; and Sidcup.

Pensioners and Treatment.

Mr. GROVES asked the Minister of Pensions what was the number of pensioners in receipt of treatment with allowances on Nov. 1st, 1923, Nov. 1st, 1924, and Nov. 1st 1925, respectively; and what was the number of men in receipt of treatment and training on the same dates and the number of pensioners who were on home treatment without allowances.—Major G. C. TRYON replied: The number of pensioners in receipt of medical treatment with allowances was: 33,019 on Nov. 1st, 1923; 30,519 on Nov. 1st, 1924; and 26,148 on Nov. 1st of the present year. The number of men in receipt of treatment and training on the same date was: 3064 in 1923 and 1313 in 1924. Owing to the diminished need for further vocational training and the consequent closure of the centres during 1924 and the present year, only 12 men who are completing a course of instruction still remain in the centres. I regret that I have no information as to the last part of the question.

Bursitis as an Industrial Disease.

Mr. TINKER asked the Home Secretary if a decision had been reached in regard to the inclusion of bursitis in the schedule of industrial diseases for miner's beat knee.—Sir WILLIAM JOYNSON-HICKS replied: Proposals for amending the present descriptions in the schedule of miner's beat knee and miner's beat elbow were referred by me in July last to the Mining Association and Miners' Federation for observations, but neither body has so far furnished me with its views on the subject and at the present moment when they are so much occupied with other matters I should be reluctant to press for a reply.

Food Preservative Regulations.

Mr. BARNES asked the Prime Minister whether, in view of the importance of the issues which would be involved if the Public Health (Preservatives, &c., in Food) Regulations, which were issued on 4th August, 1925, were put into operation, he would give time to a discussion of them in this House at an early date.—Mr. BALDWIN replied: I regret that owing to the pressure of business it is impossible to allow time for such discussion this session.

Welfare of Children.

Mr. DAY asked the Minister of Health if he was aware that no provision existed for the medical welfare of children over 2 years of age and under 5 years; and, in view of the danger of children between these ages being exposed to the risk of preventable diseases, would he cause arrangements to be made in order to close the present gap.—Mr. NEVILLE CHAMBERLAIN replied: No, Sir. The arrangements made under the Maternity and Child Welfare Act do not exclude any category of children below school age, and my department loses no opportunity of impressing upon the local authorities in charge of maternity and child welfare schemes the importance of maintaining a continuous supervision over children up to the age at which they attend school.

Unhealthy Housing Areas.

Mr. GROTRIAN asked the Minister of Health whether he was aware that local authorities were being deterred from representing areas as unhealthy owing to the unfairness of paying nothing for buildings which in themselves were unexceptionable but which happened to be within an unhealthy area; and whether he would consider the repeal of Section 46 of the Housing Act, 1925, and the putting into force of the recommendations of the report of the Unhealthy

Areas Committee, 1921.—Mr. Neville Chamberlain replied : I cannot accept the suggestion made in the first part of the question that no compensation is paid for buildings which in themselves are unexceptionable. Payment on the basis of site value is prescribed by the Act for buildings which are included in a scheme on account of their sanitary condition or because the premises are dangerous or prejudicial to health. I am closely watching the operation of this section, but I am not in a position to make any statement as to future legislation at the present time.

Powers of the General Medical Council.

Colonel Woodcock asked the Minister of Health whether his attention had been called to the recent action of the General Medical Council in striking off the Medical Register one of its members for what was described as infamous conduct in a professional respect ; whether he was aware that the General Medical Council was now composed wholly of medical members ; and whether, seeing that the statute did not require that the General Medical Council should be composed exclusively of medical men, he would in nominating members of the Council take steps to add members representing the public.—Mr. Neville Chamberlain replied : The answer to the first and second questions is in the affirmative, except that the practitioner to whom I understand my hon. and gallant friend to refer was not a member of the General Medical Council. The answer to the third question is that members of the Council, other than those representing certain bodies specified in the Acts, are nominated by His Majesty with the advice of his Privy Council. The Minister departmentally responsible is the Lord President of the Council.

Colonel Woodcock : Will he set up a committee to investigate the procedure of the Council and its relation to modern usage and methods.—Mr. Chamberlain : I am not the Minister departmentally responsible.

The General Medical Council and Dr. Lloyd.

Sir Robert Gower asked the Minister of Health whether his attention had been called to the action of the General Medical Council in removing the name of Dr. William Lloyd from the Register of medical practitioners for having given treatment to certain patients ; and whether he would consider the necessity of introducing legislation restricting the power of the General Medical Council to strike off the Medical Register the names of practitioners who had not been proved to be guilty of actual misconduct and giving him power to replace on such Register the name of any person which, in his opinion, had been capriciously or unreasonably removed. —Mr. Neville Chamberlain replied : I have consulted my noble friend the Lord President of the Council on this matter as responsibility rests with him and not with me. The name of Dr. William Lloyd was not, as I understand it, removed from the Medical Register by the General Medical Council for having given treatment to certain patients, but for having sought to obtain patients and promote his own professional advantage by unprofessional methods. I am furnishing my hon. friend with a copy of the charge on which Dr. Lloyd was summoned to appear before the Council. In answer to the second and third parts of the question I am advised that the General Medical Council have statutory power to direct the erasure from the Medical Register of the name of a practitioner who has been convicted in England or Ireland of any felony or misdemeanour or in Scotland of any crime or offence, or has, after due inquiry by the Council, been judged to have been guilty of infamous conduct in a professional respect. I am further advised that there is no evidence that the Council have directed the erasure of the name of any practitioner without his having been thus convicted or thus judged after due inquiry to have been guilty of infamous conduct in a professional respect as defined by Lord Justice Lopes, Lord Justice Davey, and Lord Esher. In regard to restoration, it has been the practice of the Council to replace names on the Medical Register when they are satisfied that such a course will not be prejudicial to the public interest. My noble friend has no reason to believe that the Council have acted capriciously or unreasonably, and as at present advised does not consider that the introduction of further legislation is necessary, there being already power under the relevant Acts for the Privy Council to issue its directions to make good any defaults in practice of the General Medical Council.

Committees and Panel Practitioners.

Lieut.-Commander Kenworthy asked the Minister of Health whether he would state the total number of committees of inquiry convened, since these committees had power to award costs, for the purpose of inquiring into a practitioner's fitness to remain on the panel ; the number of cases in which the practitioner was unsuccessful in rebutting the suggestion that he was unfit to remain on the panel ; and the amount of costs awarded to the practitioner in each case. —Mr. Neville Chamberlain replied : Since the Inquiry Committee referred to have had power to award costs, 34 inquiries have been held. In 12 cases the inquiry resulted in the practitioner being removed from the medical list, and in one case he was permitted to resign in lieu of removal. In five of these 13 cases no order was made as to costs. In 15 of the remaining cases the facts disclosed were held to justify requiring the practitioner to pay the costs or the imposition of other penalties. In three cases no order was made, and in three cases costs were awarded to the practitioners, the amounts being £35 3*s.* 4*d.*, £59 4*s.* 2*d.*, and £4 4*s.* respectively.

Poor-law Relief.

Mr. Neil Maclean asked the Minister of Health the number of people receiving poor relief in England and Wales at the end of June, August, and October, 1925.—Mr. Neville Chamberlain replied : Excluding lunatics in county and county borough asylums, casuals, and persons in receipt of domiciliary medical relief only, the number of persons in receipt of Poor-law relief in England and Wales on the last Saturday in June was 1,105,970, on the last Saturday in August, 1,200,599, and on the last Saturday in October, approximately 1,270,186.

Deaths from Tuberculosis Contracted on Active Service.

Mr. Pielou asked the Minister of Health the number of ex-Service men who had died during the last ten years from tuberculosis contracted while on active service.—Major G. C. Tryon replied : During the ten years up to Nov. 30th about 21,000 men pensioned for tuberculosis have, I regret to say, died from that disease.

FRIDAY, DEC. 4TH.

Beds in Military Hospitals.

Brigadier-General Charteris asked the Secretary of State for War the present number of equipped beds in military hospitals under the control of the War Office ; and the average daily number of patients in these hospitals during the current year.—Sir L. Worthington-Evans replied : The information is as follows : number of equipped beds at home and abroad on Oct. 31st, 1925, 6751. Average daily number occupied during the year ending Oct. 31st, 1925, 3567.

Brigadier-General Charteris asked the Secretary of State for Air the present number of equipped beds in hospitals under the Air Ministry ; and the average daily number of patients in these hospitals during the current year.—Sir S. Hoare replied : The answer to the first part of the question is 1586 ; to the second, 528. Of the 1586 equipped beds, 1139 are in hospitals in Iraq and Palestine which cater for the whole garrisons—i.e., Army as well as Air Force, and British as well as Indian troops, and, in Palestine, the British gendarmerie in addition. I may add that it is necessary to provide beds considerably in excess of the average occupation in order to be in a position to cope with epidemics, casualties, seasonal illnesses, and the special conditions under which the forces in the Middle East are serving, but their number is, and will continue to be, brought under constant review.

MONDAY, DEC. 7TH.

Medical Staff at Halton Hospital.

Sir Fredric Wise asked the Secretary of State for Air the number of boys at Halton College, and the number of tutors, doctors, &c.—Sir S. Hoare replied : The medical staff at Halton Hospital consists of 9 officers and 94 airmen, but their duties are not confined to providing medical attendance for the school, the hospital being a central one for the whole Air Force.

Neurasthenic Clinics.

Captain Waterhouse asked the Minister of Pensions what general instructions, if any, had been issued to officials with a view to cutting down the number of patients receiving treatment in neurasthenic clinics.—Lieut.-Colonel G. F. Stanley (Parliamentary Secretary of the Ministry of Pensions) replied : The general instructions in force are issued with the object of securing that all patients who require it receive appropriate and efficient treatment. The operation of the neurological clinics is under the general supervision of the deputy commissioner of medical services for neurological cases, who is a specialist, and is responsible for seeing that the treatment carried out at the various clinics is both necessary and satisfactory.

Cost of Poor-law Administration in 1924.

Mr. Rhys asked the Minister of Health the cost of Poor-law administration for 1924.—Mr. Neville Chamberlain replied : The amount expended in England and Wales during the financial year ended March 31st, 1924, on administrative charges in respect of the relief of the poor and purposes wholly connected therewith was £1,187,906.

TUESDAY, DEC. 8TH.

Beds in Naval Hospitals.

Brigadier-General CHARTERIS asked the First Lord of the Admiralty the present number of equipped beds in naval hospitals, and the average daily number of patients in these hospitals during the current year.—Mr. DAVIDSON (Parliamentary Secretary to the Admiralty) replied: The figures are as follows:—

R.N. Hospital—	Equipped beds.	Peace accommodation.
Haslar	1151	1151
Plymouth	756	860
Chatham	872	599
Portland	117	117
South Queensferry	100	100

Information as to the numbers of equipped beds in naval hospitals abroad is not available. The accommodation in these hospitals is as follows: Malta, 365; Bermuda, 78; Hong-Kong, 125; Cape, 48; Wei-Hai-Wei, 38. "Equipped beds" means actual beds and their fittings, including those kept in store, which may or may not be in excess of the amount of accommodation. The average daily numbers of patients in naval hospitals for the period Jan. 1st–Sept. 30th, 1925, were as follows. No later information is available: Haslar, 334; Plymouth, 375; Chatham, 377; Portland, 50; South Queensferry, 44; Malta, 188; Bermuda, 22; Hong-Kong, 54; Cape, 36; Wei-Hai-Wei, 11.

Small-pox at Middlesbrough.

Mr. GROVES asked the Minister of Health whether he was aware that the death from small-pox at Middlesbrough, referred to in the quarterly return of the Registrar-General, No. 306, was really due to some other disease; and whether he could give the age of the patient and state whether the patient had been vaccinated or not.—Sir KINGSLEY WOOD (Parliamentary Secretary of the Ministry of Health) replied: The only death from small-pox registered in Middlesbrough during the quarter ended June 30th, 1925, was in respect of a child aged 1 month. The cause of death given in the medical certificate was "broncho-pneumonia following small-pox," and, in accordance with the general rules, based upon international agreement, which are referred to in the reply given on August 4th last, the death was classified as being due to small-pox. The child had not been successfully vaccinated.

Appeal from the General Medical Council.

Colonel WOODCOCK asked the Prime Minister whether he was aware that a member of the medical profession who was struck off the list by the General Medical Council had no redress or appeal against such decision; and whether he was prepared to set up a committee to investigate the procedure of the Council in its relation to modern methods and usage of the medical profession regarding the Medical Act of 1858.—Major HENNESSY (Lord of the Treasury) replied: I am asked by the President of the Council to say that there is no appeal from the General Medical Council to another court, but a medical practitioner struck off the Register may, at any future session, bring up his case for revision, and his name may be, and often is, restored to the Register. In all inquiries the General Medical Council is assisted by a lawyer of great experience and ability. It has since its creation in 1858 performed the duties entrusted to it without serious criticism, and as at present advised my noble friend does not think that sufficient reason has been shown for setting up a committee of inquiry.

Colonel WOODCOCK: Is the hon. and gallant gentleman not aware that members of the Bar, solicitors, and members of all professions except the medical profession, have an independent court of appeal, and will he take steps to try to get one in this case?—Colonel SINCLAIR: Is it not a fact that practitioners struck off the roll have a right of appeal to the Privy Council, if they care to exercise it?—Major HENNESSY: I will see that Colonel Woodcock's observations are conveyed to my noble friend.

Dispensing in the Army.

Mr. HERBERT WILLIAMS asked the Secretary of State for War whether, in view of the fact that prescriptions containing dangerous drugs and poisons might be dispensed in the Royal Army Medical Corps by persons other than medical officers or pharmacists, he would give instructions that such prescriptions should in future only be dispensed by a medical officer or pharmacist, or under the direct supervision of a medical officer or pharmacist by whom the quantity of the dangerous drugs or poisons shall be checked.—Captain D. KING (Financial Secretary to the War Office) replied: All army dispensaries are under the direct supervision of a medical officer. The only persons, other than medical officers, who may make up prescriptions in these dispensaries are qualified army dispensers, and they may only make up prescriptions signed by a medical officer. I am not aware of any reason for considering that the present procedure is not satisfactory.

Medical News.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION.—A special fortnight's course in medicine, surgery, and the specialties will commence on Jan. 11th, 1926, at the Prince of Wales's General Hospital (N.E. London Post-Graduate College). On Jan. 4th the Bethlem Royal Hospital will start a series of lecture-demonstrations on Tuesdays and Thursdays at 11 A.M. on the various branches of psychological medicine, the course lasting for four weeks. On the same date the West End Hospital for Nervous Diseases will begin a month's course in neurology; lectures, including clinical demonstrations on selected cases, will be given daily at 5 P.M. The North-Eastern Fever Hospital will hold a three weeks, course in infectious fevers; this course will begin on Jan. 11th and will consist of a series of demonstrations in the diagnosis and treatment of the acute infectious diseases, at 11 A.M. on Wednesdays and Saturdays. A cardiology course will be in progress at the National Hospital for Diseases of the Heart from Jan. 11th to the 22nd. On the 18th the Queen's Hospital for Children will start a fortnight's course in diseases of children, which will include lectures, demonstrations, and operations. The first of a new series of lectures, arranged by the Fellowship of Medicine, will be given on Jan. 21st, when Dr. Herbert Spencer will lecture on Abdominal Palpations in Pregnancy. Other subjects of interest will be dealt with on subsequent Thursdays, the lectures beginning in each case at 5 P.M. A copy of each syllabus and of the general course programme will be forwarded on application to the Secretary of the Fellowship, 1, Wimpole-street, London, W.1.

TUBERCULOSIS SOCIETY.—A meeting of this society will be held to-day (Friday), at 8 P.M., at 1, Upper Montague-street, Russell-square, W.C., when Dr. Otto May will read a paper on Life Assurance and Tuberculosis.

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society will be held to-day (Friday) at the Miller General Hospital, Greenwich, S.E., at 8.45 P.M., the President, Dr. Arthur Davies, in the chair, when the Purvis Oration will be delivered by Mr. Wilfred Trotter on the Surgery of Malignant Disease of the Pharynx.

HUNTERIAN SOCIETY.—The second dinner meeting of this society will be held at Simpson's Restaurant, 2 and 3, Bird-in-Hand Court, 77, Poultry, Cheapside, on Monday, Dec. 14th, at 7.30 P.M., when a discussion on Indigestion will be opened, from the medical standpoint by Dr. J. Campbell McClure, from the surgical by Mr. H. W. Carson, and from the mental by Dr. H. Crichton-Miller.

DIPLOMA OF PSYCHOLOGICAL MEDICINE.—A course of lectures and practical work will be held at the Maudsley Hospital, Denmark Hill, London, S.E., Part I. beginning in January, 1926. Those taking part will include Sir Frederick Mott, F.R.S., under whose direction the course will be held, Mr. Charles Geary, Dr. F. Golla, Dr. Henry Devine, Dr. Bernard Hart, Dr. Edward Mapother, Dr. C. Hubert Bond, Dr. F. C. Shrubsall, and Dr. W. C. Sullivan.

THE LONDON (R.F.H.) SCHOOL OF MEDICINE FOR WOMEN.—The annual dinner was held at the Savoy Hotel, London, on Dec. 3rd, Dr. J. Walter Carr presiding. Over 300 past and present students and guests were present. Lord Riddell, the president of the Royal Free Hospital, proposed the toast of the school and hospital and said that in the near future it was proposed to establish even closer union between the London School of Medicine and that hospital. The Chairman, in response, chronicled the retirement of Dr. May Thorne from her post of honorary secretary of the school in order to have more free time to devote to the appeal fund of the hospital, and welcomed as her successor Dr. J. Aitken. During the past year, he added, a new professor of pathology had been appointed in the person of Dr. J. H. Dible; the midwifery department had been brought under the same roof as the hospital, to the great convenience of the students; and nearly 100 students had qualified from the school. Mr. C. Joll proposed the guests, Miss Wilkinson, M.P., and Prof. Yandell Henderson replying. Prof. Henderson spoke with appreciation of the equipment and efficiency of British hospitals and medical schools. In spite of the wealthy foundations of the U.S.A., the position of professors and lecturers in those schools appeared to vary little as between the two countries, and they seemed to him to be at least as well off in Great Britain. The toast of the chairman, proposed by Dr. Chodak Gregory, was received with acclamation which testified to his popularity.

THE house of the Royal Society of Medicine will be closed from Thursday, Dec. 24th, to Monday, Dec. 28th, inclusive.

Mr. C. J. S. Thompson, M.B.E., has resigned his post as Curator of the Wellcome Historical Medical Museum, with which he has been associated since its foundation.

University College Hospital, London.—Mr. S. R. Lamb, who for the last five years has been secretary of the Sheffield Joint Hospitals Council, has been appointed Appeals Secretary to University College Hospital. Mr. Lamb carried out the "Penny-in-the-Pound" scheme, which has had an important effect upon the finances of the Sheffield hospitals.

Inverness Northern Infirmary.—At a public meeting at Inverness last week it was decided to enlarge Inverness Northern Infirmary at a cost of £100,000. Dr. D. J. Mackintosh, medical superintendent of Glasgow Western Infirmary, has reported that the buildings are antiquated, and has made proposals for the construction of new wards, the existing erections to be retained for administrative purposes and nurses' accommodation. The Northern Infirmary draws patients from all over the Highlands, and nine cases out of ten are surgical.

New Isolation Ward at Northampton.—Last week the Marquess of Exeter, Lord Lieutenant of the county, opened a new isolation block at Northampton General Hospital. The new wards are named after Sir James Crockett, who has defrayed a large proportion of their cost. An anonymous gift of £5000 has enabled the hospital to provide what Mr. Reginald B. Loder, the chairman of the board of management, described as "the very best electrical and X ray department in the whole of the United Kingdom." Since the war £50,000 has been spent in improving and extending the hospital.

The late Mr. Robert Owen, L.R.C.P. & S. Edin. The death has taken place of Mr. Robert Owen, of Penygroes, N. Wales, in his sixty-sixth year. He obtained his medical education at the Anderson College, Glasgow, qualified in 1892, and was a resident house physician at the Royal Infirmary, Glasgow. He took an active part in civic affairs, being a past chairman and alderman of the Carnarvonshire County Council, and chairman of the Joint Police Committee. He had a deep interest in the cause of charity in his district, and his death will be felt as a great loss. He leaves one daughter, who is married.

Birmingham Medical School: Centenary Celebrations.—A special Degree Congregation was held on Dec. 8th at the University, Edgbaston, to celebrate the centenary of the Birmingham Medical School. In the unavoidable absence of the Chancellor, Lord Cecil, the Vice-Chancellor, Sir Gilbert Barling, presided. A message was sent from the Congregation to the Chancellor of encouragement in his great work on disarmament at the League of Nations session at Geneva. The Principal, before presenting the honorary degrees, thanked Sir Charles Hyde for his magnificent gift to the University of £100,000. For the honorary degree of Doctor of Laws were presented: Mr. Neville Chamberlain, M.P., Sir Donald MacAlister, Sir Humphry Rolleston, and Prof. Priestley Smith. Mr. Chamberlain, in his address, referred to his long family and personal connexion with the University. "The University," he said "sets an example of enlightened civic action." The history of the Birmingham Medical School he described as a history of development and evolution, in spite of obstacles, to a position where it was now quite indispensable to the city. He reviewed the extent of public medical services in this country; the School Medical Service employed 1500 doctors, the Health Insurance Scheme treated 14,000,000 people and employed 13,000 doctors. He continued: "I desire to stress that the value of this vast organ of public service, coupled as it is with private service, is not fixed but depends on the persons engaged in it; the value of such an organisation depends on its power to attract to itself the best type of man who can only be produced by adequately equipped and adequately managed medical schools." He went on to indicate the lines along which progress might be made by extending post-graduate teaching and research, by reinforcing the existing local Cancer Board and the Board of Medical Research, and by keeping the public informed of the needs and hopes of the school.

In the evening a reception was held in the Great Hall by the Vice-Chancellor, the Principal, Mr. C. Grant Robertson, and the Dean of the Faculty of Medicine, Mr. W. F. Haslam. Amongst the notable medical exhibits set out for inspection were the portraits of Mr. William Sands Cox, F.R.S., founder of the Medical School and Queen's Hospital; of John Ashe, the founder of the General Hospital (1793); and of George Freer, surgeon to the General Hospital, who was the first surgeon successfully to ligature the external iliac artery for aneurysm. Side by side were to be seen a modern operating theatre completely equipped, and one of Lister's time, with the actual spray and table used by him and later by Sir William Macewen. Among many other arresting exhibits should be noted an admirable series of dissections of the cardiac auriculo-ventricular bundle, and a series of specimens showing the madder method of research on bone development.

International Tuberculosis Conference.—The next International Conference will be held at Washington, U.S.A., on Sept. 30th, Oct. 1st and 2nd, 1926. The International Union against Tuberculosis was founded in 1920. The headquarters are in Paris and in close relationship with the League of Red Cross Societies. Tuberculosis conferences under the auspices of the Union have been held at Paris (1920), London (1921), Brussels (1922), and Lausanne (1924). Subjects of great interest and exchange of ideas and methods for dealing with tuberculosis have been considered at these conferences, which are attended by leading scientists from all over the world. The International Union is directed by representatives of all the national tuberculosis associations, or in the absence of such association by representatives of the Government, of the countries within the League of Nations and the United States of America. Each country is represented on the Council of the Union by a definite number of representatives, Great Britain having five such official delegates. The conferences are open to members of the public on application to the respective National Association, and on payment of a small fee. At the forthcoming conference the subjects chosen for discussion are: (1) the part played by contagion in tuberculosis among adults; (2) anatomical structure of tubercle, from histogenesis to cavity; (3) tuberculosis and milk. Further particulars may be obtained from the Secretary, National Association for the Prevention of Tuberculosis, 20, Hanover-square, London, W. 1.

Manchester Cancer Hospital and Research Campaign.—The thirty-third annual report of the Christie Hospital (Cancer Pavilion and Home) states that the total of patients under treatment numbered 450 and the operations performed 323. The gifts and bequests amounted to about £18,000, including one of £3500 and three of £1000 each. The committee approves of the suggestions of the Cancer Research Committee as to coöperation with other institutions, and that the income from the Christie Hospital funds specially earmarked for this work should be pooled, but stipulates that the headquarters of the work should be at Manchester University, and that each institution should be represented on the Cancer Research Board in proportion to the funds it provides. The report of the medical board states that the youngest patient admitted during the year was 14 years of age, the oldest 84, and the average age 49. Of the 406 new in-patients, 112 were inhabitants of Manchester and 23 of Salford. A large proportion of the patients had been treated by radium. Mr. Wilson H. Hey, honorary surgeon to the hospital, said that in the Manchester district there were a million people of 40 years and over, and of this number they knew that 100,000 would die of cancer. Cancer did not attack the weak, but the strong and healthy. At present, though it seemed hardly believable, there were not 12 whole-time cancer research workers in these islands. We could not expect an early result with so few workers on this or any other obscure problem. Prof. R. B. Wild emphasised the fact that the local cancer committee was raising a separate fund in order to investigate what wanted investigation very much—the local conditions under which cases of cancer occurred, the environment of the patients, their occupations, their houses, and many other things. It was announced that the board of management had decided to extend the hospital.

University of Liverpool.—At the meeting of the University Court on Nov. 30th it was stated that students' fees met only one-third of the running cost of the University. In the current year the University would receive £11,200 additional grant from the Treasury, representing part of the University grant cut off under the Geddes axe. The Cheshire County Council had agreed to increase their grant from £300 to £1000, and the Lancashire County Council would in all probability raise their grant from £2000 to £4000. A warm tribute was paid to the untiring single-handed fight of Prof. J. Share-Jones, director of veterinary studies, extending over a period of 20 years, to secure Government recognition of veterinary science in a university. The Development Commissioners have decided to make a grant up to £15,000, on a pound-to-pound basis, for the erection of new buildings for the veterinary school. This is the first occasion on which funds have been offered from a Government source for the provision of buildings in the University. The expenditure on the general account is now in the neighbourhood of

£200,000, as compared with £80,000 only ten years ago. Vice-Chancellor J. G. Adami, in his report, stated that the number of women entering medicine had declined until it had reached almost vanishing point. The reduction was explained by the fact that women poured into the medical schools during the later years of the war and until three years ago, only to discover when they graduated after the war that it was almost impossible to obtain posts. The falling off in the number of dental students was a grave matter, for the country was in need of well-qualified dentists. The Act of 1920, with the object of preventing the extension of unqualified practice, demanded four years spent in training with relatively high fees. The question was whether it did not raise the requirements of qualification above the economic level, and while this was in doubt, the General Medical Council demands the equivalent of an additional year of study of pre-registration chemistry and physics. Throughout the country the admissions to dental schools had fallen to an alarming degree. An inquiry made in the summer term brought to light the fact that out of 1750 full-time students only 300 at the most indulged in sports and games. The time was ripe, and indeed overdue, Dr. Adami held, for the compulsory medical or physical examination of all students—men and women—upon admission, and periodically in later years, by a qualified medical staff, who would advise students regarding any special form of exercise and special care to be taken in individual cases.

Donations and Bequests.—Sir James Crockett has given £500 (£5500 in all) to Northampton Hospital extension.—Miss Catherine Beatrice Muntz, Tunbridge Wells, besides other bequests, left £2000 upon trust to assist young lads suffering from incurable disease, and £100 to the British Home for Incurables, and £50 each to a large number of charitable institutions.—Miss Agnes Ann Best, Cleveland-square, W., left £1000 to Manchester Royal Eye Hospital, and £250 each to St. Bartholomew's Hospital and the Paddington Green Children's Hospital.—Sir Charles Hyde, Bart., has given unconditionally a contribution of £100,000 to the University of Birmingham, and has left the spending of it entirely to the discretion of the Council of the University.—In celebration of his seventy-fifth birthday Mr. Bernhard Baron, of Hove, Sussex, has distributed £50,000 among hospitals and charitable institutions, and the Home for Aged Jews and three London Hospitals—Guy's, St. Thomas's, and St. Bartholomew's—receive each £2000, and the following £1000 each—viz.: Royal Northern Hospital, Hospital for Sick Children (Great Ormond-street), Royal Free Hospital, City of London Hospital for Diseases of the Heart and Lungs (Victoria Park), West London Hospital, Westminster Hospital, Royal London Ophthalmic Hospital (Moorfields Eye Hospital), University College Hospital, Brompton (Consumption) Hospital, St. Mary's Hospital (Paddington), St. George's Hospital, Home for Aged Jews (Home of Rest Building Fund), Rockefeller Foundation Gift for Obstetric Hospital, Prince of Wales's General Hospital (Tottenham), Reedham Orphanage, National Children's Home and Orphanage, Dr. Barnardo's Homes, Jewish Board of Guardians, Greater London Fund for the Blind, Salvation Army (Maternity Home), and British Legion (Earl Haig's Fund).

Appointments.

Masterman, L. Margaret T., M.B., B.S. Lond., has been appointed Assistant Medical Officer, Selly Oak Hospital, Birmingham.

Queen Charlotte's Maternity Hospital, Marylebone-road, N.W.: Hamilton, G. E. R., M.R.C.S., L.R.C.P. Lond., M.B., B.S., Senior Resident Medical Officer; Davies, Vyvyan J., M.R.C.S., L.R.C.P. Lond., Assistant Resident Medical Officer.

Westminster Hospital: Bell, P. S., M.R.C.S., L.R.C.P. Lond., and Jones, D., M.R.C.S., L.R.C.P. Lond., House Physicians; Davies, J., M.R.C.S., L.R.C.P. Lond., and Rubra, E. J., M.R.C.S., L.R.C.P. Lond., House Surgeons; and Daniel, G. M., M.R.C.S., L.R.C.P. Lond., Resident Obstetric Assistant.

Vacancies.

For further information refer to the advertisement columns.

Alexandria Municipality.—Chief Bacteriologist. L.E.900.
Bangor, Carnarvonshire, and Anglesey Infirmary.—H.S. £200.
Bath Ear, Nose, and Throat Hospital.—Hon. Dental S.
Bombay, Gokuldas Tejpal Hospital.—Hon. P. and two Hon. S.'s.
Bridge of Weir, near Glasgow, Consumption Sanatoria of Scotland.—Res. Med. Asst. £200–£250.
Brighton, New Sussex Hospital for Women and Children.—Radiologist. £100.
Brighton, Royal Sussex County Hospital.—Third Hon. Anæsthetist.
Bristol General Hospital.—Hon. Asst. S. to Ear, Nose, and Throat Dept.
Bury Infirmary.—Jun. H.S. £150.
Cancer Hospital, Fulham-road, S.W.—H.S. At rate of £100.
Chichester, Royal West Sussex Hospital.—Jun. H.S. £150.
City of London Hospital for Dis. of Heart, &c., Victoria Park, E.—P. to Out-patients.
Coventry and Warwickshire Hospital.—H.S. £135.
Dreadnought Hospital, Greenwich, S.E.—H.P. and H.S. Each at rate of £110.
Durham, Holywood Hall Sanatorium.—Med. Supt. £850.
East London Hospital for Children and Dispensary for Women, Shadwell, E.—Morning Cas. O. At rate of £120. Also H.S. At rate of £125.
Herefordshire General Hospital.—Hon. Orthopædic S.
Hospital for Sick Children, Great Ormond-street, W.C.—Res. Med. Supt. £300. Also H.S. £50.
Liverpool University.—Lecturer in Anatomy. £400.
Liverpool, Walton Institution, Rice Lane.—Res. Asst. M.O. £200.
London Homœopathic Hospital, Great Ormond-street, W.C.—Three Res. M.O.'s. At rate of £100.
London Hospital, E.—Asst. Obstet. and Gynæcological S.
Manchester, Monsall Hospital for Infectious Diseases.—Jun. Med. Asst. £350.
Middlesex Hospital and Medical School, W.—Two Surgical and One Medical Registrarships. Each £300.
Middlesex Hospital Medical School, W.—Cancer Research Scholarships. Each £150.
Mount Vernon Hospital, Northwood, Middlesex.—Jun. Res. M.O. £150.
Norwich, Norfolk and Norwich Hospital.—Res. Anæsthetist. £150.
Nottingham General Hospital.—Res. Cas. O. At rate of £200.
Oldham Royal Infirmary.—H.S.'s. Each at rate of £200.
Plaistow Fever Hospital, E.—Second Asst. M.O. £200.
Portsmouth Royal Hospital.—Third H.S. and Cas. O. At rate of £150 and £100 respectively.
Queen Mary's Hospital for the East End, Stratford, E.—Res. M.O., H.P. Two H.S.'s. Obstet. H.S. H.P. And Cas. O.
Royal Free Hospital, Gray's Inn-road, W.C.—Dist. Obstet. Asst. £100.
Royal London Ophthalmic Hospital, City-road, E.C.—Refraction Asst. £100.
St. Bartholomew's Hospital.—Asst. Ophth. S.
St. Mark's Hospital for Cancer, &c., City-road, E.C.—Anasthetist. £25.
St. Mary's Hospital, Institute of Pathology and Research.—Research Studentship. At rate of £200.
St. Peter's Hospital for Stone, &c., Henrietta-street, Covent-garden, W.C.—Clin. Asst.
Salford Royal Hospital.—Cas. H.S. At rate of £125.
Salisbury General Infirmary.—Hon. Ophth. S.
Scarborough Hospital and Dispensary.—Two H.S.'s. Each £126.
Sheffield Royal Infirmary.—Ophth. H.S. £80.
South London Hospital for Women, South Side, Clapham Common, S.W.—Clin. Assts.
Talgarth, Breconshire, Mid-Wales Counties Mental Hospital.—Asst. M.O. £350.
Willesden General Hospital, Harlesden-road, N.W.—Gynæcologist. Also Hon. P. to Out-patients.

The Chief Inspector of Factories, Home Office, London, S.W., announces vacant appointments for Certifying Factory Surgeons at Oxted, Surrey, and Tenbury, Worcestershire.

Births, Marriages, and Deaths.

BIRTHS.

Crowden.—On Nov. 29th, at Croyland, Edgware, the wife of Guy Pascoe Crowden, B.Sc., M.R.C.S., of a son.

Harvey.—On Nov. 26th, at 12, Western Hill, Durham, the wife of Dr. Charles A. Harvey, of a son.

Hughes.—At Lahore, India, on Nov. 17th, 1925, the wife of Major T. A. Hughes, I.M.S., of a son.

DEATHS.

Bate.—On Dec. 1st, at King Edward-road, South Hackney, E., George Paddock Bate, C.B.E., M.D., aged 82 years.

Clarke.—On Nov. 27th, at Woburn-square, W.C., George Mouat Keith Clarke, M.R.C.S., L.R.C.P., formerly of Gerrard-street, W., and Invercargill, N.Z., in his 88th year.

Davis.—On Nov. 25th, at Malone Park, Belfast, Lieut.-Colonel R. E. S. Davis, I.M.S., late Civil Surgeon, Rangoon, Burma.

Green.—On Dec. 1st, at Airhill, Glanworth, Co. Cork, Lieut.-Colonel James Sullivan Green, late R.A.M.C., aged 64.

Shaw.—On Dec. 2nd, at Dunstan-road, Golders Green, Oliver Shaw, M.D., late of Moseley, aged 71.

Thomas.—On Nov. 29th, Philip Marsden Thomas, L.S.A., L.R.C.P.I., L.M., L.D.S., F.P.S.G., of Thornton-avenue, S.W., aged 61.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Monday, Dec. 14th.

WAR: at 5 P.M.
Paper:
Surg.-Commander J. L. Priston, R.N.: The Prevention of Scurvy in the Royal Navy.

Tuesday, Dec. 15th.

GENERAL MEETING OF FELLOWS: at 5.30 P.M.

Wednesday, Dec. 16th.

HISTORY OF MEDICINE: at 5 P.M.
Paper:
Dr. J. D. Rolleston: Voltaire and Medicine (Part II.).

Thursday, Dec. 17th.

DERMATOLOGY: at 5 P.M. (Cases at 4 P.M.)
Cases:
Dr. H. C. Semon: Multiple Idiopathic Sarcoma (Kaposi).
Dr. Barber: Lupus Pernio showing Result of Treatment with Carbon Arc Lamp.
Other cases will be shown.

DERMATOLOGY.
STUDY OF DISEASE IN CHILDREN. } at 8.30 P.M.
Discussion on
The Ætiology and Treatment of Infantile Eczema.
Speakers:
Dr. H. C. Cameron and Dr. F. Langmead (for the Section for the Study of Disease in Children).
Dr. A. M. H. Gray (for the Section of Dermatology).

Friday, Dec. 18th.

ELECTRO-THERAPEUTICS: at 8.30 P.M.
Papers:
Dr. R. E. Roberts and Dr. Morris J. Cohen (Liverpool): Paget's Disease of Bone.
Dr. P. J. Briggs (New Lodge Clinic): Methods of Examination of the Pelvic Cæcum.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.
MONDAY, Dec. 14th.—8.30 P.M., Discussion on the Treatment of Genito-Urinary Tuberculosis in the Male, to be introduced by Mr. Cyril A. R. Nitch, followed by Mr. Kenneth M. Walker, Dr. Stephen R. Gloyne, and others.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square.
THURSDAY, Dec. 17th.—8.15 P.M., Sir Thomas Carey Evans: Paper on the Surgical Aspects of Amœbiasis. Discussion to be opened by Major K. K. Chatterji, of Calcutta. Lantern slides will be shown preceded by a demonstration at 7.45 P.M.

CHELSEA CLINICAL SOCIETY.
TUESDAY, Dec. 15th.—8.30 P.M. (in the Board Room of St. George's Hospital), Colonel W. L. Watt and Mr. S. Forsdike: Discussion on Deep X Ray and Radium Treatment.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.
MONDAY, Dec. 14th, to SATURDAY, Dec. 19th.—Lecture Room of the Medical Society, 11, Chandos-street, W. Sir John Thomson-Walker will deliver a lecture on Urinary Tuberculosis at 5.30 P.M. This lecture is open to all members of the medical profession free of charge.—HAMPSTEAD GENERAL HOSPITAL, Haverstock-hill, N.W. Second week of a Course in General Medicine, Surgery, and the Specialties. Daily, 4.30 to 6 P.M. Lectures and demonstrations.—HOSPITAL FOR DISEASES OF THE SKIN, Blackfriars-road, S.E. Course in Skin Diseases, second week. Instruction in the Out-patient Dept. every afternoon from 2.30, and a Venereal Clinic Tuesday and Friday, 5 P.M. All information as to fees, &c., from the Secretary of the Fellowship.

QUEEN CHARLOTTE'S MATERNITY HOSPITAL, Marylebone-road, N.W.
THURSDAY, Dec. 17th.—5 P.M., Mr. L. Williams: Albuminuria of Pregnancy.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.
FRIDAY, Dec. 18th.—4 P.M., Dr. Dan McKenzie: Early Mastoid Operations.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, Dec. 16th.—4 P.M., Prof. L. McIlroy: The Results and Prevention of Puerperal Sepsis.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, Dec. 15th.—4.15 P.M., Dr. A. H. Holmes: Disorders of the Thyroid Gland.
FRIDAY.—4.15 P.M., Sir William Milligan: Modern Technique in the Diagnosis and Treatment of Foreign Bodies Impacted in the Air Passages.

JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, St. Andrews.
TUESDAY, Dec. 15th.—4 P.M., Prof. A. Patrick: The Treatment of Diabetes.

Notes, Comments, and Abstracts.

THE HYGIENE OF MENSTRUATION.

AN AUTHORITATIVE STATEMENT.

A STATEMENT, based on the published observations of doctors who have had opportunities of examining large numbers of girls, has been issued under the auspices of the Medical Women's Federation.[1] It is intended primarily for the use of schoolmistresses and parents, and should serve to make clear the modern view that a girl during the time of menstruation should not be considered "unwell." Its terms are as follows:—

> Menstruation is a natural function; it is not an illness, and girls should therefore continue their ordinary work and play during the period. It should not be and is not normally accompanied by pain or malaise.
>
> There is no risk in taking a bath during the period; in fact it is desirable that a warm bath should be taken daily. It is a good remedy for any slight pain or headache which may occur. Where the girl is accustomed to a daily cold bath this may be continued during the period, but for obvious reasons swimming in public baths cannot be allowed.
>
> It is important that there should be a daily action of the bowels.
>
> There is no risk in allowing a girl to join in ordinary games and gymnastics. Exercise, especially exercise involving bending of the body, has been found in many cases to lessen or cure menstrual pain. The practice of giving alcohol in any form at these times is most inadvisable.
>
> Girls should not be allowed to get into the habit of resting or lying down at this time. It has been found by medical officers of girls' schools that this leads to menstrual pain and malaise, which does not occur when girls continue their ordinary games, walks, and other exercise.
>
> While it is desirable that girls should take part in games, long expeditions or cycle rides, or matches or competitions in which there is a strong incentive to exhaust the reserves of strength should be indulged in with some caution, especially during the early years of adolescence.
>
> If a girl suffers from pain or other disability, it is a sign that there is something wrong, and it is essential that a doctor should be consulted. The underlying conditions are much more easily cured at the onset.

The advice is sound, especially the recommendation to discourage girls from lying down or resting during these periods as a routine measure. If attention is focused on any slight discomfort it will assuredly be looked for, whereas if little disturbance of ordinary life is the rule, few girls will be found to require special measures.

THE INFLUENCE ON HEREDITY OF JEWISH CUSTOMS.

IN the course of a lecture delivered on Dec. 5th at the Whitechapel Art Gallery under the auspices of the Jewish Health Organisation of Great Britain Dr. Redcliffe N. Salaman discussed heredity as a factor in public health. He spoke of the inheritance of mental deficiency, as exemplified in one deplorable family record, contrasting it with the incidence of ability and high character shown, for example, in the Darwin-Galton-Wedgwood family. Here, in five generations, besides numerous men of high character and civic worth, occurred 16 men of highest rank in science, and the women-folk include a well-known poetess and others of outstanding ability. Considering what these two types of families mean to the nation, Dr. Salaman said that a mental defective who lived to the age of 50, and was cared for by the public authorities, could not cost the State less than £5000, whilst the indirect loss occasioned by such an individual probably reached a similar amount. Sterilisation of mental defectives was probably beyond the limit which public opinion would sanction, and possibly beyond what science would to-day be inclined to dictate. The Jewish community might, however, make a register of such persons, and keep them under surveyance, in order that any defective children might at once be segregated. This would enable them to learn more of the nature of heredity of such troubles, and when sufficient information had been collected the necessary measures could be taken to prevent the increase of such defects. It might seem to many that proposals to segregate individuals for life, or to abolish their power of activity, was too drastic a remedy. If any who thought this would but inquire what it already costs the nation to maintain these unfortunates in careful segregation till the age of 16, only to allow them to propagate their kind when they regained freedom, they would see good reason to alter their views. But even without legislation much could be done. Parents of children who are epileptic or are deficient in any way should do their utmost to prevent their children from marrying. In Jewish circles marriage had been considered with such veneration that even degenerates had been forced into the marriage state. It was to this practice that they owed the lamentable fact that their community contained such a large proportion of mentally unfit. It was, however, right to point out that the fact that the percentage of highly gifted was also abnormally high in their midst, was also due to heredity, and to their anxious pursuit of the marriage state. The old custom of marrying the rich man's daughter to the most promising student of the Yeshibah was one of the most successful and illuminating eugenic experiments ever conceived. The time had now come when, whilst adhering to all that was sound in the old, they must advocate new methods in order to promote the betterment, moral and physical, of mankind.

ESKIMOS AND THEIR HEALTH.

IN a description[1] of the health of the Eskimos, Dr. S. K. Hutton, who has spent seven years in Northern Labrador, first outlines the climate, the food, and habits of life. The climate is comparatively regular; the excessive cold of winter only giving place for a few short weeks to summer. The only break in the regularity is the sudden occurrence for three or four days of a period of thaw in either February or March. Eskimo dietary is mainly flesh and fish; vegetable foods are decidedly scanty. They cultivate no plants, but obtain in autumn a small black watery berry which is stored in barrels and allowed to freeze for winter store. Of flesh that of seal is the most important, and is eaten raw and full of blood; fish also, in the warmer part of the year, is obtained in plenty and is eaten fresh, often raw or dried, without salt. Cod-liver oil is used considerably; dried fish is dipped in it. The dietary is rich in vitamins, with the exception of the anti-scorbutic vitamins. The Eskimo lives a life of activity and strain. He has great power of withstanding fatigue, and is inured to exposure to the weather. His house is small, ill-ventilated, dirty, and ill-smelling—a dark and noisome den. Refuse is simply thrown out of the door where, fortunately, it freezes—but in summer it thaws. Promiscuous consanguinity prevails.

The Eskimo possesses a low resisting power to disease; few live beyond 60, those few are aged and feeble. They possess a tendency to hæmorrhage, of which epistaxis, menorrhagia, and hæmoptysis are the most common form, the latter quite distinct from that of pulmonary tuberculosis. These hæmorrhages indicate a scorbutic condition, and lime juice is the most effective remedy. Although the Eskimos will run far and fast without affecting their pulse-rate, and endure laborious toil, when they are seized with illness cardiac debility becomes pronounced. Similar debility occurs during confinement, but only prolongs the process, which is usually simple and uneventful. Typical scurvy is rare, but the scorbutic tendency is common, particularly if the berry crop fails, as it did in 1904–5. Then "kallak," a pustular skin eruption, broke out, but it gave way to anti-scorbutic treatment. The tendency to suppuration is pronounced; nearly all cases of mumps end in suppuration, as do many ordinary bruises. Typhus appeared once, but was fortunately quickly eradicated, for lice are common in Eskimo huts. Tuberculosis is not widespread, but attacks certain families, who are carried off with "galloping consumption"; it is a very fatal disease, and death may result in about six weeks from onset. Diseases of the nervous system are not common, with the one exception of paralysis of the facial nerve due to cold winds. Occasionally drunkenness occurs, but chronic alcoholism is unknown. Epilepsy occurs among the Eskimos, but insanity is uncommon, even though the mental balance is unstable. Inguinal hernia is uncommon, but a form of small epigastric hernia occurs in males. The commonest eye disease is pterygium, attributable to the irritating effect of strong light; it occurs more frequently in women than in men, since the man wears glasses to protect him from snow-glare, while the woman often just goes out of the dark hut into the bright light without glasses. Snow-blindness is common among children, but it always ends in recovery. Dr. Hutton never saw a case of malignant new growth, nor of rickets. Babies suckle often for two years, and any mother feeds any child. For the most part Eskimos are very sensitive to drugs, normal doses being poisonous to them. Mercury is an exception. Influenza is endemic, and does not appear to have been introduced from without. It arises annually in February with the short seasonal thaw, and again in August. Its origin is ascribed to the method of refuse disposal; specially interesting instances of outbreaks are given. The disease may be bronchial, gastric, or meningitic, varying in epidemics; the gastric form is the most fatal.

A disease which is causing great damage to the Eskimos is syphilis, which was brought back by a party of Eskimos who had been exported for exhibition purposes. Although its introduction is recent, the ravages it is causing do not compare in severity with those which followed its introduction in Europe. Primary symptoms tend to be somewhat indefinite; but the secondary manifestations are clear, except that a secondary rash is rare. The disease is so recent that tertiary manifestations have not, it is said, yet had time to develop. The full-blooded meat-eating Eskimos seem to have a natural protection against it. Child mortality is excessive, and is no new thing, since the ancient burying places are full of children's graves; but it appears to be getting worse. Even those that survive the first year run serious risk during the ages 3 to 5. The main causes of this great mortality among Eskimo children lie in constitutional debility and lack of resisting power to disease. Dr. Hutton discusses the future of the Eskimos, and feels uncertain whether, as Europeanisation spreads, the race will survive.

This monograph contains much valuable material presented as the result of first-hand observation. Illustrations are lacking, but these can be found by consulting an excellent article[2] recently published on the MacMillan Arctic Expedition.

THE HEALTH OF AN ARMY IN THE FIELD.

HEALTH was well represented in the wireless programmes on Dec. 4th, with "Hygiene in the Kitchen" from Oslo, "Hygiene" from Paris, and, above all, Sir W. B. Leishman, in London, on the "Health of an Army in the Field." Diseases, said the Director-General, were more dangerous to soldiers than were wounds. Wellington lost 460,000 men in the Peninsular campaigns, only 60,000 of them from wounds. To keep an army healthy is a laborious and never-ending toil. Formerly there were five who died of disease to each one killed by the enemy; but in the Great War, of the 739,000 who were killed or died, only 84,000 died of disease, 8 in battle to 1 of disease, a triumph for the medical service. Recruits when taken in were carefully trained physically, made thoroughly healthy and tough; surely they would remain healthy? Far from it. Dangers are greater than before; so many more men are engaged. Freedom of communication allows exotic disease to disseminate more freely; there were 14 theatres of war, in many of which troops of various races were employed. To what was the medical victory due? To five particular lines of policy. (1) Food. By the self-sacrifice of those at home the army had in plenty, but as the usual foodstuffs became unattainable the difficult adjustments needed to keep the ration balanced were made possible by research. (2) Water was often difficult to obtain, but safe supplies were ensured from dangerous sources by filtration and chlorination. (3) Hygiene and sanitation were carefully watched, on the march, in villages, in the trenches, with ever-increasing warfare against flies. Our army had advantage over others in that the responsibility for the sanitation of units is, with us, shared by the commanding officer and the medical officer. Our men had good clothing and baths, and their vermin were destroyed. (4) Disease was detected early by pathologists at every hospital, and in mobile laboratories up almost to the fighting line. Quick detection of epidemic diseases is of the first importance to prevent spread, whether by infection, by food, or by bad water. (5) Inoculation. Vaccination prevented small-pox; typhoid, the disease we most feared, was held in check by inoculation. The French, who did not at first inoculate, had in the first nine months 7036 deaths from typhoid, while England had but 208 in the whole war. But that we had so well devised methods for preventing disease, the losses of the war would have been infinitely worse.

GIFTS TO MIDDLESEX HOSPITAL.—A "Rejected lover who has no more use for them" has sent to the Middlesex Hospital two gold and platinum brooches to be sold for the benefit of the rebuilding fund.

A HOSPITAL SCHOOL.—At the Northcourt Hospital for Sick Children in College-crescent, Hampstead, the London County Council conducts a handicraft school for children between 4 and 15 years of age. There are at present 34 children in the school, who are taught needlework, basket-making, knitting, and similar crafts during their convalescence. The hospital was established half a century ago for the treatment of children suffering from chronic or incurable diseases of an aggravated character.

Two Lectures
ON THE
EFFICIENCY OF THE HEART
AND ITS MEASUREMENT.

University of London Advanced Lectures in Physiology, delivered at University College, Nov. 30th and Dec. 1st, 1925,

BY YANDELL HENDERSON,
PROFESSOR OF APPLIED PHYSIOLOGY, YALE UNIVERSITY.

LECTURE I.*—THE MEANING AND CONDITIONS OF EFFICIENCY.

THE conception of the efficiency of the heart which is now current in clinical medicine falls far short of being as definite as is desirable. It is essentially qualitative. None of the tests now available, or employed by physicians, approach a real measurement of the supremely important function of the power of the heart. The physician applies his stethoscope at various points on the chest and listens. He percusses and thus outlines roughly an area of dullness. He has the subject change from the recumbent to the erect position. He has him step up and down on a chair, or climb a flight of stairs, and he notes the alteration of pulse-rate and arterial pressure. He notes also—and this is really a more significant test than any other—whether the patient is out of breath on moderate exertion. But all these tests, valuable as they are in the absence of any means of estimation more precise, do not constitute an adequate measurement of the efficiency of the heart.

The heart is a pump. As with any other pump there is only one form of measurement that is direct and absolute—viz., measurement of the volume discharged by each stroke of the pump, or taking the rate of beat into account, the volume pumped per minute. Hitherto there has been no method available, except for quite special laboratory purposes, for measuring in litres a minute the volume of blood that the heart of a man, woman, or child, sick or well, resting or working, actually pumps in a minute. Fortunately, a method[1] has recently become available by which this measurement can be made quickly, easily, and on anyone; a method suitable alike to the laboratory or to clinical purposes.

In the second lecture we shall consider some of the results already obtained with this method. But first, what should we understand by the term "efficiency of the heart"? What is it that the heart has to do? Evidently the heart does not exist and act simply for itself. It is not only a pump. It is also the chief respiratory organ of the body. It determines the supply of oxygen to the body and thus fixes the maximal amount of energy available for the body's use.

RELATION OF THE CIRCULATION TO RESPIRATORY METABOLISM.

Modern physics, which only a little while ago drew a hard-and-fast distinction between matter and energy, now tells us that, fundamentally, matter is energy. In the living body there is one sort of matter, one element, which to all intents and purposes is energy. That element is oxygen. Each litre of oxygen absorbed in the lungs becomes for the use of the body almost exactly 4·8 large calories. The maximum theoretical variation is only from 4·7 calories, when the litre of oxygen is used to burn fat, up to 5·05 calories per litre, when it burns sugar. For all physiological purposes, therefore, the most convenient unit of energy is the litre of oxygen. Thus the power supplied to the body by an athlete's heart is about four litres of oxygen a minute, or in ordinary units of energy, 20 large calories a minute. This seems to be about the maximum quantity that can be withdrawn from the air of the lungs and transmitted to the labouring muscles.

Both in clinical medicine and in physiology there are two subjects which now are studied quite independently. The heart is one. The other is the energetics and gaseous exchange of the body, especially in the procedure of basal metabolism. Neither in clinic nor laboratory are these two subjects now associated except in a vague and hypothetical fashion. This is the greatest gap and defect now existing in both fields. Neither data nor methods have been available for the quantitative correlation of the volume of blood pumped by the heart, in all sorts of people, well or ill, with the respiratory exchange and energy expenditure. The object of these two lectures is, now that data and a method are available, to present a conception of the circulation and the heart based quantitatively on respiratory metabolism.

EFFICIENCY OF THE LUNGS.

The pumping power of the heart is, indeed, not the only element or stage in the passage of oxygen from the air to the tissues at which the flow of oxygen might be limited. It might be asked whether a man can breathe in and out of his lungs in one minute a sufficient volume of air to ventilate fully the maximum amount of blood that the heart can pump through the lungs. The figures for the volume of blood pumped by the heart, as determined by the new method above referred to, are 5 to 7 litres per minute during bodily rest, and 25 to 30 litres of blood flowing through the lungs in a minute during vigorous muscular work. The figures for respiration are 6 to 8 litres of air breathed during rest and 60 to 80 or even 100 or more as the actually observed volumes inhaled and exhaled by a vigorous man doing hard work. Evidently a man can breathe far more air than the amount corresponding to even the largest increase in the rate of circulation of the blood. Thus, when a man is out of breath, as we call it, from running, his trouble is not fundamentally in the inability of his chest muscles and the diaphragm, working on his lungs, to draw in and exhale enough air. The real limitation is in his circulation, that is, in the pumping power of his heart, and in the transportation of oxygen and CO_2 by the blood. Similarly, the patient with cardiac disease usually has no sensations that he refers to his heart, but reports that he is "short of breath," although it is essentially his blood pump, not his air pump, that is defective.

Air might be drawn into the lungs in sufficient amount and yet the diffusion of gases through the membranes of the lungs into the blood might be so slow that, during hard work, the blood rushing through in a torrent four or five times as fast as during bodily rest would be incompletely oxygenated. Space forbids dealing here with the literature of this topic. I have for some years past been engaged in investigations on the absorption and elimination of volatile substances through the lungs. The evidence convinces me that, at least during full normal breathing, diffusion between the air and the blood in the lungs is virtually instantaneous. With any volatile substance the equilibrium of pressure in the gaseous phase in the air and in the dissolved phase in the arterial blood flowing from the lungs is at all times virtually complete. A. and M. Krogh have, indeed, reached a somewhat different conclusion on the basis of a method devised originally by Bohr for measuring the "diffusion constant" of the lung by the diffusion of carbon monoxide; but Dr. J. S. Haldane tells me, and I mention it by his permission, that, in work not yet published, he finds that the diffusion of carbon monoxide is so rapid and complete that he also is led to estimate diffusion through the lung membranes as normally affording an almost instantaneous equilibrium between the air and the blood in the lungs.

Of course this condition does not hold when the lungs have been rendered œdematous by an irritant gas; and practically it ceases to apply in shallow breathing, as, for example, in pneumonia. But the practical point is whether or not the power of an athlete or a normal working man is ever limited by the slowness of the diffusion of oxygen through his lungs. That this is not the case we can infer with certainty from an observation which everyone has made or can easily verify. It is that, even during the most intense physical exertion, the lips, ears, and cheeks of a normal man never show the faintest trace of cyanosis. A fact like this, one that can be observed and verified in everyday life, outweighs as evidence any amount of experimental laboratory demonstration that it ought not to be so.

---

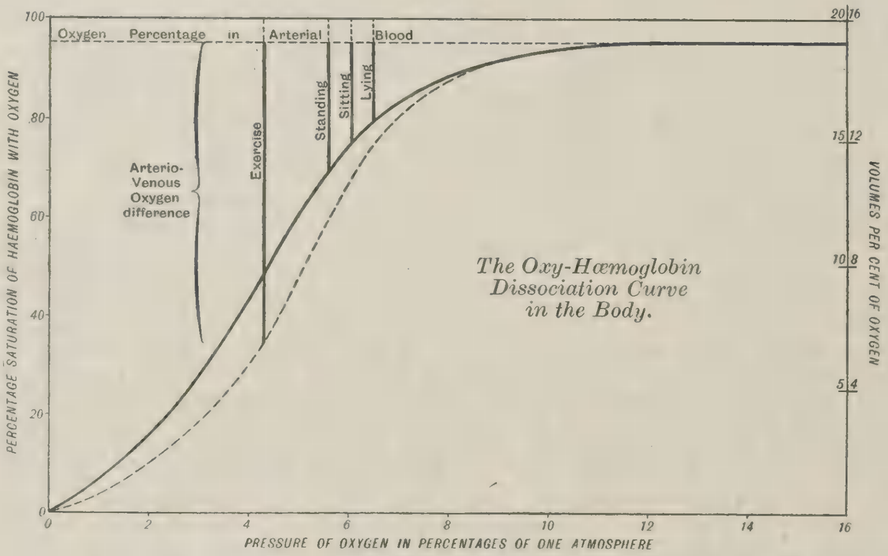
* Lecture II. will appear in a coming issue of THE LANCET.

[1] Henderson and Haggard: Amer. Jour. Phys., 1925, lxxiii., 193.

OXYGEN TRANSPORTATION BY THE BLOOD.

The amount of oxygen that the heart can send to the tissues is limited by the oxygen capacity of the blood. According to the Haldane standard 18·5 c.cm. of oxygen is the maximum in 100 c.cm. of normal blood. It would be truer to say that the normal range is between 16 and 20 c.cm. of oxygen in 100 c.cm. of blood. But 100 c.cm. of blood pumped by the heart do not represent 18·5 c.cm. (or 16 or 20) of oxygen available for the work of the tissues. Some of it, ranging from a sixth to a quarter, we may call high pressure oxygen, and this is all that is used during bodily rest. During heavy and continuous muscular work (such as digging with pickaxe and shovel) a much larger percentage is used, and we may call this medium pressure oxygen, because the larger the utilisation the lower falls the pressure. Finally, during extreme exertions such as an athlete makes in a contest, 60 or 70 per cent. may be utilised—that is, 12 or 14 c.cm. of oxygen may be consumed by the tissues from each 100 c.cm. of blood; and this we may call low pressure oxygen.

FIG. 1.



In Fig. 1 are reproduced the oxyhæmoglobin dissociation curve in the body (after Christiansen, Douglas, and Haldane) with some additions to illustrate its application in this connexion. The broken line is approximately the probable form of the curve during vigorous muscular exertion. The upright lines show approximately the amount of oxygen withdrawn in the tissues—that is, the arterio-venous oxygen difference. With the new method of measuring the circulation we find that approximately, during bodily rest, lying down, the amount is 3 volumes per cent.; sitting it is 4; standing it is 5 or more; during heavy work it is 7 or 8; and with intense exertion it is 12 volumes per cent. or more. The pressures corresponding to these amounts of oxygen are to be read from the scale below the abscissa.

From this figure we see that, if in a patient with heart disease the total consumption of oxygen by the body remains normal at the usual basal metabolism for his size and age, and if the efficiency of his heart is so reduced that it pumps only two-thirds of the normal volume per minute, then the arterio-venous oxygen difference will be 50 per cent. greater than in a normal man, and the patient will experience a marked decrease in his capacity for muscular exertion. In fact, we find in ambulant but easily winded cardiac patients that measurements of the circulation in sitting rest show about two-thirds of the normal blood-stream. Thus the large blood flow supplied by the normal heart is important because it affords an ample supply of high pressure oxygen in the tissue capillaries. In fact, the arterio-venous oxygen difference is the best possible index and measure of functional efficiency of the heart.

It is, however, probable that each tissue has a specific oxygen difference of its own. That of muscle is large, as L. Hill and Nabarro have shown. Thus the increase of the general arterio-venous oxygen difference for the body as a whole during work is apparently due in large part to the relatively greater proportion of blood flowing through the muscles.

THE ARTERIO-VENOUS OXYGEN DIFFERENCE.

Unfortunately, this is a figure which can only be calculated when every other factor has been measured. To determine it directly on a man would require that some blood should be drawn direct from an artery and its content of oxygen determined by analysis; and also that a long needle of a hypodermic syringe should be thrust through the chest wall into the right side of the heart so as to withdraw for analysis a sample of the mixed venous blood which it contains. The difference in the oxygen contents of these two samples would show the relation of the blood flow and oxygen transportation to the body's oxygen consumption. Blood from a peripheral vein, such as one in the arm, does not serve the purpose, because it comes from only a limited and special area and not from the body as a whole. Blood can be withdrawn from the heart of an animal without causing any pain or injury, and I have a friend in America, an enthusiastic young investigator, who is willing and anxious to have cardiac puncture done on himself, but his associates decline. Fortunately, the figure for the arterio-venous oxygen difference can now be calculated for a man on the basis of a determination of his oxygen consumption and of his circulation. The one divided by the other gives the arterio-venous oxygen difference.

The last stage in the passage of oxygen to the tissues is its diffusion from the blood in the capillaries into the working cells and especially into the muscle-fibres. As Krogh has pointed out, the force which causes diffusion from the blood into the tissues is the difference in the pressure of oxygen. The higher the pressure of oxygen the more rapid the diffusion. But the pressure of oxygen in the capillary blood is dependent upon the volume of the blood flow; a relatively large flow means a relatively large supply of oxygen and hence a relatively high oxygen pressure. When, on the contrary, the volume of blood flowing through the tissues is small in relation to the oxygen there consumed, its pressure falls far down on the oxyhæmoglobin dissociation curve. Thus, the volume of blood pumped by the heart is the fundamental factor in the pressure of oxygen in the capillaries.

The normal value or amount of the arterio-venous oxygen difference in all vigorous mammals, such as dogs, men, and horses, is closely correlated with the intense metabolism required in warm-blooded animals. The value is probably nearly the same throughout the range of mammals of all sizes. Determinations in my laboratory have shown that this is certainly the case for dogs and men, from very small dogs up to very large men. The value is of the order of 3 or 4 volumes per cent. For inactive species of animals—e.g., the goat—it is probably larger. It is not dependent upon the animal's size, that is, its weight, nor upon its skin area, total metabolism, and energy expenditure, but is probably a fundamental mammalian constant. It is one of the vital constants, like the osmotic pressure and hydrogen-ion concentration of the blood, and its sugar-content, or body temperature, arterial pressure, and so on. Physiologically, health may be defined as the maintenance of all such "vital constants" within the range of their normal variations. A single figure for any one of them is quite unjustifiable and misleading. They vary within a normal range. Disease is the perversion of one or more of them to a value beyond the normal range.

The Volume of the Circulation.

The approximate uniformity of the arterio-venous oxygen difference affords an absolute arithmetical proof of another important fact—namely, that the circulation in all vigorous active mammals of all sizes during rest is about 25 to 30 litres of blood pumped by the heart for each litre of oxygen consumed in the body's metabolism.

This conclusion in turn leads to another, for if the basal metabolism, normal for a man or animal, determines the amount of blood flowing through the lungs during bodily rest, we next ask the question: What determines the individual's basal metabolism? The answer to this question is afforded by Rubner's law that all mammals have approximately (i.e., within a certain range) the same amount of heat production, and therefore the same oxygen consumption, per unit of skin surface. On this account small animals have a very high metabolism for their body-weight. Mice have many times as great a skin surface, exposed to the cooling action of the atmosphere per gramme of weight, as men have. So a mouse eats his own weight of food in about as many days as a man does months. The volumes of air that are breathed by mice and men, and the volumes of oxygen that they consume, are in the same proportion. Even for human beings of various sizes, men, women, and children, it has been shown by Benedict, and particularly by Du Bois, that it is not body-weight that underlies the basal metabolic rate and therefore the resting oxygen consumption; but that the main factor is skin surface.

So we arrive inevitably at the conclusion that the rapidity of the circulation, that is, the pumping activity of the heart in healthy men and animals, is not proportional to their body-weights, but in general (for animals corresponding in other respects, especially activity and vigour) to their surfaces, that is, their skin areas. And we see that small mammals and small people must have relatively large circulations and relatively active hearts per kilo of body-weight. The circulation index, as we term it, for man, and probably for all vigorous active mammals of all sizes, is of the general magnitude of 3 or 4 litres of blood per minute per square metre of skin. For lethargic, but non-hibernating, mammals of all sizes it is probably about a third less per square metre.

The next question is: How does the heart of a small mammal or a small person accomplish this relatively greater pumping action? How in larger subjects is the pumping relatively less? The volume of blood that the heart drives to the lungs each minute in any individual is the arithmetical product of two factors: (1) The number of heart-beats in a minute, that is, the pulse-rate; and (2) the volume of blood discharged by each beat, that is, the so-called stroke volume. But for animals of different sizes, for people of different weights, and for both people and animals during the variations of activity of sleep and work, and extreme muscular activity, we wish to know whether and to what extent each of these factors is varied. The pulse, fortunately, is easily counted. But the stroke volume is less easily obtained. Indeed, what we want to know is: (1) How the stroke volume varies in animals and especially in people of different weights; and (2) how it varies in an individual when he passes from rest into various degrees of muscular activity. These are separate problems and must be discussed separately.

The resting or basal stroke volume in large and small animals and in large and small people, is it determined by body-weight or by body surface? Of course, the larger the stroke volume that a heart makes, the larger that heart has to be. If, then, small and large animals had hearts proportional in size to their skins, the hearts of such animals as men and horses would be quite small organs in relation to the size of the thorax, while the hearts of mice and rats would be so large as to fill the entire chest cavity. In fact, however, if the cross section of the thorax of a small mammal is projected by means of a stereoptical lantern on the screen and beside it is thrown the cross section of the thorax of a large mammal of corresponding vigour, the hearts are seen to be approximately of the same size. Thus the size of the heart is in general correlated with an animal's body-weight (subject to the proviso of corresponding vigour) and not with its surface. The ratio of heart-weight to body-weight (as I am informed by Prof. A. J. Clark, who is preparing a review of this subject in the Cambridge Comparative Physiology series) is nearly the same in the rat, cat, pig, sheep, ox, and elephant. All of these are animals incapable of prolonged rapid running, and have therefore smaller hearts than such vigorous animals as dogs, men, and horses. On the physiological side the relation between the stroke volume of the heart and the body-weight for vigorous mammals, from small dogs up to large men, has been worked out in my laboratory. We find that, in all healthy, vigorous individuals during bodily rest, the heart throws out at each beat approximately 1·4 to 1·8 c.cm. of blood for each kilo of body-weight. This quantity needs a name, so we call it the resting or basal "stroke index." Vigorous, active men and animals have larger stroke indices than those which are lethargic. The relatively slow animals (rat to elephant) probably have a stroke index about a third smaller.

So we conclude that: (1) the basal circulations of vigorous mammals of all sizes are proportional to their surfaces; and that (2) the stroke volumes are proportional, not to their surfaces, but to their body-weights; or, more precisely expressed, the stroke index for all vigorous men and animals of all sizes is probably about the same—namely, 1·4 to 1·8 c.cm.

Evidently the basal or resting pulse-rates for men and animals of corresponding vigour must be functions, not of body-weight, but of the ratio of body surface to weight. In general the data available verify this deduction. The resting pulse-rate for a horse is about 40 per minute, for a vigorous man about 60, for medium-sized dogs about 110, for cats considerably more, and for quite small animals many hundred beats per minute. In general, as Miss Buchanan [2] found some years ago and as Prof. A. J. Clark shows in the review which he has kindly allowed me to see in manuscript, when the vigour and activity of the species and individual are allowed for, the pulse-rate is found in accord with the surface weight ratio.

Three Reserves of the Circulation.

The variations in the circulation of an individual, for example an athlete, when he is at rest or exercising moderately or making a maximum exertion in a contest, is a more difficult problem to estimate. The circulation has three possible reserves: (1) the pulse-rate may be accelerated; (2) the arterio-venous oxygen difference may be increased; and (3) the stroke volume of the beats may be augmented.

---

[2] Buchanan, F.: Science Progress, July, 1910, No. 17, p. 60.

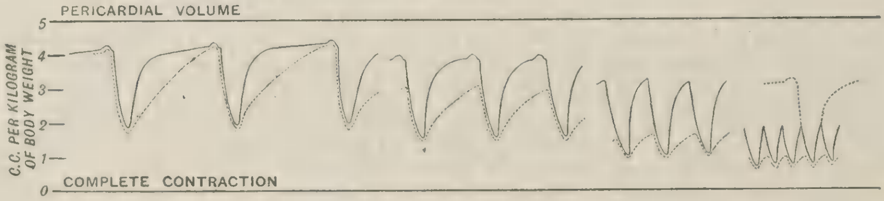
The pulse is accelerated by even the slightest muscular exertion, even in the most vigorous men. This acceleration is usually roughly, apart from the factor of mental excitement, proportional to the oxygen consumed for degrees of activity from a state of complete rest up to that of quietly moving about one's room or office or laboratory. With increased exertion, such as walking at a fair pace, and still more for considerable muscular efforts, the evidence from a number of lines of observation makes it certain that the second factor, the arterio-venous oxygen difference, is drawn on. The venous blood contains less oxygen during work than during rest. The character of the variations in the third reserve of the heart, the stroke volume, has long been the most important and most difficult problem of the circulation. Does the heart not only beat faster but also discharge a larger volume at each stroke when the individual is working, in comparison to the stroke volume when he is resting?

As this topic will have to be considered rather fully in the second lecture, we may leave it until then. Indeed, before we attempt to consider the answer and its significance we must first take into account certain mechanical conditions which affect the stroke of the heart.

Limits of the Stroke Volume.

One of these conditions is the capacity of the pericardial sac. It amounts to about 7 to 10 c.cm. per kilo body-weight, or a maximum stroke for each side of the heart of 3·5 to 5 c.cm. per kilo body-weight. The ventricles never, during normal activity, contract down to the obliteration of their cavities, but some blood remains in them. It is probable that during diastole they never expand to such an extent that the pericardial sac is brought taut, except possibly coincidentally with heart strain. The normal relations are shown in Fig. 2.

FIG. 2.



Measurement of the circulation and of the stroke volume was one of the chief objects of one of the greatest of the schools of physiology, that of Ludwig and his pupils and their many followers in all lands where physiology is studied. The direct results of all the work of all these investigators are, however, in respect to this particular topic, extremely meagre and misleading. If we examine critically all their data (as I had occasion to do recently in preparing a review[3] upon which I am drawing in this lecture) we find that the stroke index of the resting mammal would be of the magnitude of 0·5 c.cm. or even 0·3 c.cm. But if we calculate the volume of circulation that this would give a man of moderate size it comes to only 1 or 2 litres a minute; and if we take into account the oxygen consumed by such a person even under basal conditions in bed at complete rest, we find that such a circulation would barely carry enough oxygen, or at a stroke index of 0·3 c.cm. would not carry enough oxygen to keep him alive.

Although the results of classical physiology are thus seen to be of no validity on the great problem to which they were primarily directed, they are of immense value for the light they throw on another matter of scarcely less importance—namely, how the vital mechanism runs down to its final standstill; in other words, the process by which the great majority of men and animals die what we call "natural deaths." It is by a progressive decrease of the circulation and particularly by decrease of the stroke volume of the heart. This is the way that patients die after surgical operations—the process of shock; it is also usually the termination of acute disease. Arterial pressure is not the element of primary failure, for its controlling mechanism, the vasomotor nervous system, is functionally capable until near the end. Nor is it the contractile power of the heart that fails; for in animals under experiment and in patients nearing death, the infusion of fluid into a vein, in quantity sufficient to supply the right heart momentarily with a nearly normal volume, is responded to by the heart with beats of nearly normal amplitude. It is thus in the venous return to the heart that we find the factor that fails progressively. The heart can pump into the arterial system no more than the volume of blood that the venous return from the body supplies.

The Veno-Pressor Mechanism.

The veno-pressor mechanism is a topic at once important and difficult. Apparently the blood vascular system consists of two main parts: (1) the arteries and arterioles whose tonus is controlled by the vaso-motor nervous system, essentially as Claude Bernard defined it; and (2) the capillaries and veins. Failure of the first of these is manifested as syncope or fainting; failure of the second is what is loosely termed shock of the traumatic, toxæmic, acapnial, histamine, and other varieties.

The mechanism controlling the venous return is still obscure, but during health its activity is obviously correlated with the gaseous exchange in the tissues. When a man exercises, the production of carbon dioxide in his tissues is increased, and so also the venous pressure and the venous return are augmented. Moderate exercise, while breathing air containing 4 to 6 per cent. of carbon dioxide, induces an enormous dilatation of the veins and a very high venous pressure. Contrariwise in patients after a prolonged surgical operation under open ether anæsthesia with over-ventilation of the blood and consequent acapnia, the skin is pallid, the veins imperceptible, and the circulation much decreased. In patients in this condition inhalation of carbon dioxide in air or oxygen restores a pink colour to the skin; the veins, such as the jugular, again become visible and a full pulse and normal arterial pressure soon return.

The Meter of the Circulation.

For our present purpose the important relation is that between venous pressure and the extent to which the right ventricle is filled and distended in diastole. It is the right ventricle which acts as the meter of the circulation, while the left ventricle serves as a force pump to drive against arterial pressure whatever quantity the right measures off to it. It is probable that, whenever the left ventricle fails to pump onward easily as large a volume as the right heart sends to it, pulmonary congestion results. In fact, the relative diastolic distensibility of the two ventricles is probably the principal condition controlling and regulating the volume of blood in the lungs.

It is always necessary to be cautious and critical regarding evidence from experiments on animals under operative conditions, and particularly those on excised organs and tissues, like the perfused heart and in general toward what Haldane terms "fragments of frogs and other animals." Observations on such fragments have not the direct validity of observations on an organ or tissue when functioning normally in the whole live animal or man under real conditions. But as regards a preparation of the heart outside the body, we now have criteria for estimating whether it is acting approximately normally; it must make effective strokes of 1·5 to 2·0 c.cm. per kilo body-weight of the animal from which the heart was taken, and it must do this when supplied with blood under venous pressures no greater than those which occur in the body. The amount of carbon dioxide in the blood is an important factor in determining the diastolic distensibility of the heart.

---

[3] Henderson: Physiological Reviews, 1923, iii., 165.

In perfused hearts which fulfilled these requirements, Prince and I [4] succeeded in measuring the stroke volumes of the two ventricles separately under various venous distending pressures. From zero up to slightly more than a normal resting venous pressure, the stroke volume of the right ventricle varied in proportion to the pressure. Above that pressure there was no appreciable increase of stroke volume. The left ventricle behaved quite differently. From zero pressure up to a moderate afferent pressure the cavity was not distended at all, and no blood was pumped. With further rise of the pressure (corresponding to that in the pulmonary veins) the strokes increased progressively, until at fairly high pressures the left ventricle made much larger strokes than any of which the right ventricle was at all capable. This behaviour of the left ventricle seemed to us to afford an explanation of why the lungs are never drained of all blood by an excessive activity of the left ventricle, and never in health over-distended and congested by relatively insufficient activity by the left ventricle. It adjusts its strokes automatically to the pulmonary blood pressure and thus takes no more nor less than the right heart measures to it.

Many years ago I obtained on dogs volume curves of the two ventricles together. The chest had been opened so as to allow the adjustment of a plethysmograph or cardiometer connected with a large, light, loosely-covered tambour. In Fig. 2 are shown types of such volume curves and their graduation in cubic centimetres per beat per kilo body-weight. The solid lines show the strokes at various rates of beat when the volume and pressure of the venous return were adequate and normal. The dotted lines (except the large stroke at the right) show the slow filling and decreased amplitude of beat under subnormal venous pressure.

SIZE OF THE HEART IN DIASTOLE.

It would, indeed, be a case of "bringing coals to Newcastle" for me to discuss this topic further here (at University College), where Prof. Starling, his associates, and pupils have made such extensive and valuable contributions to this very topic by means of the heart-lung preparation. As summarised by Starling in his Linacre lecture, the law of the heart defining the relation of the amplitude of stroke to the pressure and volume of the venous return to the heart is as follows: Within physiological limits the larger the stroke volume of the heart the greater are the energy of its contractions and the amount of chemical change at each contraction. In other words, the energy of contraction, however measured, is dependent upon the length of the muscle-fibres. Any increase in the extent of active surface increases the energy of change, exactly as in striated muscle. Thus the uniformity of stroke volume against varying arterial pressures, which all investigators have found, depends upon the fact that, while the first few heart-beats after a rise of pressure are slightly subnormal in amount, the consequent increase of the volume of blood in the heart calls into play greater power of contraction. In a similar way this law explains the capacity of the heart to accept widely varying amounts of blood from the venous system, and to increase the amplitude of its stroke so as to pump the whole increased volume from the venous side over into the arteries.

As it applies to the heart of a normal animal or man passing from rest into muscular activity, this general principle will need to be reconciled, as it doubtless will be, with evidence from an entirely different line of investigation—namely, observations by means of the X ray.[5] According to Bruns, in Germany, and Meek and Eyster, in America, the heart shadow is not larger during physical exercise, although the venous pressure is certainly increased over its resting value. If, then, the shadow is a reliable index of changes in the volume of the heart, we must suppose that an increase of stroke volume during physical work is effected by the ventricles contracting more completely in systole; a response for which the law of the heart also provides, although not so directly as it would if the size of the heart were increased in diastole by the increased venous pressure during muscular work.

There is another point which must be considered—namely, that the heart during its systolic contraction and diastolic expansion does not obey the law of the cube, as is usually assumed. If its shape during all phases of its activity were the same, its volume would vary as the cube, and its shadow as the square, of any linear dimension. The volume curve of the ventricles would then differ widely from the form of curve expressing the shortening of the cardiac muscle-fibres. In fact, however, it is well known that the volume curve of the ventricle (as in Fig. 2) has almost exactly the same form as the isotonic contraction curves of striated and of cardiac muscle. This fact seems to indicate that the heart does not contract and expand symmetrically in all diameters. If this interpretation is correct it adds considerably to the already difficult quantitative interpretation of the heart's X ray shadow as a measure of volume in three dimensions, from observation of the shadow which has only two dimensions.

In the volume curves of the heart (as in Fig. 2) both the systolic and the diastolic volumes are decreased, coincidently with increased tonus, during rapid rates of beat.

CONCLUSIONS.

The only adequate expression of the efficiency of the heart is one based on accurate measurement of the volume of blood that the heart pumps and upon the amount of oxygen consumed by the body. The relation between these two functions determines the arterio-venous oxygen difference, and thus determines the amount, and particularly the pressure of the oxygen-supply to the working tissues of the body. In vigorous mammals of all sizes the arterio-venous oxygen difference during bodily rest is about 3 or 4 volumes per cent.

The volume of the circulation in vigorous men and animals at rest is about 3 to 4 litres of blood per minute per square metre of skin surface. The stroke volume for animals and men of corresponding activity is a function of their body-weights not their surfaces. For all vigorous mammals, including man, the stroke index during rest is about 1·4 to 1·8 c.cm. per kilo per beat. The pulse-rate is in general proportional to to surface weight ratio and is thus in general an index of the intensity of respiratory metabolism.

The mechanical conditions of the heart's activity and its own behaviour make the right ventricle the meter of the circulation. The size of the stroke of this meter depends on the volume and pressure of the venous return. The veno-pressor mechanism is adjusted to act in relation to the intensity of the gaseous exchange of the tissues.

SOCIAL INSURANCE CONFERENCE.—This conference, organised by the League of Nations Union, was held on Nov. 23rd to 26th. An average of 300 people attended the sessions. Among the speakers were Sir William Beveridge, Sir Kingsley Wood, M.P., Miss Ellen Wilkinson, M.P., Sir Lynden Macassey, Sir Thomas Neill, Dr. Marion Phillips, Sir Henry Slesser, M.P., Sir Arthur Newsholme, Mr. Arthur Hayday, M.P., Sir Alfred Mond, M.P., and Lady Astor, M.P. Distinguished foreigners included Mr. Oudegeest, Secretary of the International Federation of Trades Unions, Signor Foscolo Bargoni, Director of Social Insurance at Rome, and Dr. Stephen Bauer, Secretary of the International Association for Labour Legislation. The proceedings and speeches have been published in book form and are on sale at the League of Nations Union, 15, Grosvenor-crescent, London, S.W. 1.

THE CLINICAL ASPECTS OF ISCHÆMIC NECROSIS OF THE HEART MUSCLE.[*]

By ALEXANDER GEORGE GIBSON,
M.D. Oxf., F.R.C.P. Lond.,
HON. PHYSICIAN TO THE RADCLIFFE INFIRMARY, OXFORD.

Ischæmic necrosis, or, as named by Ziegler, myomalacia cordis, is the result of blockage of the circulation in the artery supplying the part affected. Only within comparatively modern times has it been referred to disease or obstruction in the coronary arteries; Jenner was the first to point out the connexion between angina pectoris and disease of the coronary arteries. Steven (Glasgow), writing in The Lancet of 1887, was one of the first, if not the first, to make the association of coronary disease and ischæmic necrosis. Occlusion of the coronary arteries may occur from embolism, or thrombosis, from calcification or fibrosis of the wall. If the occlusion is sudden and the patient lives long enough, the coronary arteries being functional end arteries, the area affected becomes a pale infarct, which by gradual absorption becomes a fibrous scar, and then remains a contracted or depressed portion of the cardiac wall. If the occlusion be slow it is probable that fibrous tissue replaces the muscular tissue gradually without the intervention of a stage of necrosis that could be recognised by the naked eye. Two other important events may happen in the process: first, the formation of clot on the inner aspect of the necrosis, which by normal or vigorous cardiac action may become detached, forming emboli; secondly, the heart wall may be so weakened as to induce rupture. A series of well-authenticated and adequately described cases have been collected and are set down in the accompanying table.

The cases include those in which blockage of arteries is implied by the anatomical appearances, by whatever cause; but it has been my endeavour to exclude all cases in which other lesions or processes coincident with the primary one of blockage of a coronary artery might interfere with the symptoms due to the local condition in the heart, such as septic embolism, syphilis, fibrosis from causes not clearly due to arterial ischæmia, such as rheumatic. Though an extensive survey of the literature has been made the cases here set down are samples rather than an exhaustive collection. Also all consideration is omitted of occlusion of the very small arteries which may give rise to minute patches of fibrosis.

In so far as blockage of arteries may be the result of many causes, ischæmic necrosis is not confined to one period of life; the youngest case I have found was a man of 23 reported by Osler[1] in 1891. In one of my own series of post-mortems, a female aged 25, who showed hysterical symptoms following an attack of influenza, died suddenly, and was found to have thrombosis of her pelvic veins and an embolus of a coronary artery with typical ischæmic necrosis. But the larger number of cases met with are the result of the arteriosclerotic lesions, and it really therefore becomes a study of the senile heart.

The branches of the right and left coronary arteries are relatively constant in their distribution, and seeing that different parts of the heart have a different function, it might be thought that diagnosis of lesions of the various branches might be possible during life. Deductions of the site of the lesion in the heart from the symptoms are very unreliable.

There have been many attempts to classify the effects of occlusion of the coronary arteries or their branches, whether such be identified from actual blockage discovered in the artery, or from its effects—ischæmic necrosis or fibrosis. Sudden death was one of the first effects to be recognised by Wilks and Hale-White; then was added chronic cardiac failure, and if we exclude the work of Jenner and of Allan Burns, angina pectoris. But this classification by no means exhausts the possibilities, and in the list of cases abstracted a few extra groups are added, but this obviously does not complete the symptom groups which may appear.

Pathology and Symptomatology.

It is evident from these cases that there is no constancy in the effect of occlusion of various branches. In one case *occlusion* of the *anterior branch* of the left coronary produces *sudden death*, in another *angina*, in another *chronic* cardiac failure, in another no symptoms at all; in one of these latent cases in which ischæmic necrosis was discovered after death, a careful inquiry into the history of the patient revealed no hint of any illness or temporary disability in which occlusion might have taken place, nor any evidence of cardiac failure. If we omit Mackenzie's Case 7 of angina pectoris with pain in the abdomen, all the other cases of angina were the result of blockage of the anterior branch of the left coronary. Most of the cases of sudden death will be seen to show cardiac fibrosis without other evidence for acute cardiac failure. Very recent ischæmic necrosis is liable to be missed in the presence of a large fibrous lesion. If ischæmic necrosis has occurred in one artery it is likely to occur in another, and in one case I have observed there was fibrosis and very recent ischæmic necrosis in the neighbourhood. Other changes might also be present, such as a sudden implication of the bundle system. There appears to be no relation between the size of the lesion and the severity of the symptoms.

One case, No. 38 in the table, deserves a more extended description in so far as he was attended by me for several years, and the symptoms of the patient during life could be referred to the cardiac lesions found.

He was a clergyman, and had led a very strenuous athletic though healthy life as a schoolmaster. In December 1915, when aged 64, he was seen following a fainting attack there were then no signs of disease and after a few days rest he was about again. These recurred at long intervals In January, 1917, he took ether well for the removal o a rodent ulcer of the pinna. In June, 1918, when aged 67 he had a fainting attack while riding a bicycle and had t be brought home in a cab. Seen immediately he was pale collapsed, slightly hyperpnœic, and restless, with a puls that was irregular in rhythm, tension, and volume. I mad the diagnosis of coronary artery disease, took a serious vie of the outlook, and suggested a very careful life with stric limitation of exercise. Sir William Osler saw him with m and with greater clinical wisdom, as he appeared to b recovering, suggested exercise in moderation and discon tinuance of his usual morning run. He made a rapid recover and was about his work in ten days. From that time h suffered from no serious illness until in May, 1923, havin breakfasted in his usual health, he was found dead in th afternoon, having died suddenly.

The heart showed a large patch of fibrosis, obviously th result of ischæmic necrosis, in the posterior part of th interventricular septum and the posterior ventricular wa in the field of the right coronary artery, and a very recen patch of ischæmic necrosis, in the same arterial field, in th septum. The main coronary arteries were patent bu atheromatous, and there was marked atheroma of the aort There was no evidence of syphilis. It can scarcely b doubted that the old healed cardiac lesion is the evidenc of the cardiac attack in 1918 which kept him in bed for ove a week, and, this being granted, the subsequent history evidence of complete restoration of cardiac function aft the attack.

Only three of the cases in the table show evidenc of embolism elsewhere; when, however, we see th deposition of clot on the inner aspect of the heart wal we cannot be in doubt as to the frequency in thes cases of embolism. Embolism of a cerebral arter causing hemiplegia might be very misleading if were the first symptom of ischæmic necrosis. Th same is true in my case (No. 30) of embolism of a mesenteric artery that was sent to a surgical ward. I would go so far as to say that an affection of the heart in elderly persons with cerebral symptoms is presumptive evidence of ischæmic necrosis. The following case will illustrate what I mean, but unfortunately I have no post-mortem evidence.

---

[*] This paper embodies a discussion introduced by the writer at a recent meeting of the Cardiac Club, together with certain case reports which have been kindly supplied by some of its members—viz., Dr. John Cowan, Prof. F. R. Fraser, and Dr. K. D. Wilkinson. The cases contributed by Dr. Carey Coombs will appear later in a separate paper.

[1] Trans. Path. Soc., Philadelphia, 1891, xiv., 125.

A farmer of 70, previously healthy and busy in his work, one morning on going into the bathroom to wash, felt faint and a pain came on in the left groin. His doctor found a lump there and sent him to a surgeon. Two days after the left leg was very much swollen, blue, colder than the right leg, and there was some rigidity in the left iliac fossa. There was marked pulsation in the lower part of the abdomen below the umbilicus, but no pulsation in the arteries of the left foot. The heart was overacting, causing at each systole movement of the whole chest and part of the abdomen. There was some dilatation; no murmurs were heard over the heart, but a systolic murmur and the second sound was heard over the whole of the abdomen. Two days after this there was some difficulty in passing urine, and he died suddenly after an epileptic seizure affecting the left side of the body, probably an embolism.

In a recent paper[2] McNee has drawn attention to several features of ischæmic necrosis and reports two cases. The pain when present is constant and of long duration; it may be præcordial, behind the xiphisternum or in the right or left quadrant of the abdomen; it may simulate perforated gastric or duodenal ulcer, gall-stone colic or acute pancreatitis. He describes the facies of the patient during the attacks of abdominal pain as that of anxiety, of an earthy colour with some cyanosis, comparable to shock, but persisting long after the pain and distress have subsided. Pericardial friction is an important physical sign: and there is frequently a polymorph leucocytosis.

Diagnosis.

How are we to detect this lesion? The first requisite is a clear knowledge of the *anatomical process*, and to have it in mind in approaching a cardiac case in any person over 40. We ought, I think, to be secretly ashamed if we are reduced to diagnose mitral regurgitation or cardiac dilatation or even auricular fibrillation without a hint of ætiology. We are most likely to be right in a diagnosis of ischæmic necrosis in angina if we take care to exclude certain obvious possibilities such as aneurysm. *Chronic cardiac failure in old people* in the absence of syphilis, old rheumatic affections of the heart, and pernicious anæmia is almost certainly due to ischæmic necrosis. *Chronic cardiac failure plus evidence of aseptic embolism* makes the diagnosis of ischæmic necrosis practically certain.

The pulse gives help occasionally. Mackenzie has noticed in two of his cases pulsus alternans; one of my cases had fibrillation, another, at the time of the nitial lesion, irregularity in rhythm and volume probably due to fibrillation. The pulse has been recorded both fast and slow. The pulse, therefore, may give some import of cardiac failure, but can give nothing else.

The first sound of the heart is frequently poor in quality or even absent. The electrocardiogram has been explored as a means of getting greater accuracy. Carter drew attention to the direction of the notched R waves, which were found to be opposite in leads 1 and 3, and to the T wave being in direction opposite to the initial peaks, giving it he name arborisation block. The very careful report with electrocardiograms of Drury in *Heart* as proved that these results of Carter are not invariable, and in this Drury's results are in keeping with experiments on the dog's heart. A current aper by Cowan and Bramwell[3] is highly suggestive hat bundle branch block is frequently present in hese lesions.

Though much work has been done and many xcellent cases are on record, I venture to think that there is an enormous field still for the study of cardiac ymptoms and their correlation with anatomical sions.

Clinical Records: Dr. John Cowan's Cases.

CASE A.—J. S., male, aged 51 (19/7/24–24/7/24). Gradual and increasing cardiac failure, pain in the lower chest and upper abdomen at first. Aneurysm of left ventricle involving apex, inter-ventricular septum, and anterior wall. Fibrosis, thrombosis, pericarditis.

His ill-health only dated back to December, 1923, when he first began to suffer from pains in the upper part of the abdomen and discomfort over the chest. He stopped work for a week and then continued at work until the end of the year. In January a cough ensued and he was not able to resume work after the holidays, as he was short of breath. In February he had a double pneumonia. In March his feet became swollen and all his symptoms were exaggerated.

On admission he was very ill, with œdema extending as high up as the chest, the right leg being more swollen than the other parts. The swelling ceased at Poupart's ligament, and its appearance suggested an inflammatory condition superimposed upon œdema. He was very short of breath, and orthopnœic. Cheyne-Stokes breathing was present at night. There were râles at the bases. The heart was slightly dilated, the sounds weak but apparently pure. The arteries were notably sclerosed, but the fundus of the eye seemed normal. The urine contained albumin in large amount. The blood pressure was about 150 max., 105 min. Pulse, quite regular, about 100. There were old scars on the left tibia which was thickened, sepsis having obtained for many years in early life. Death ensued five days after admission.

Post-mortem examination showed an aneurysm of the left ventricle involving the apex, the interventricular septum, and a portion of the anterior wall, with extensive deposits of recent and mixed thrombus in the interior. The ventricular wall round the aneurysm was notably fibrous. The apex and the adjacent part of the anterior wall were definitely bulging, and over this was subacute pericarditis. The aortic valves showed some diffuse thickening, the other valves were normal. The aorta showed a few patches of atheroma and marked arteriosclerotic changes. The coronary arteries showed extreme atheromatous changes, and the left was plugged with a recent thrombus. Interstitial nephritis was present. A firm cicatrix involved the right iliac artery and vein at the point where the ureter crosses them. The artery above this was dilated. The vein was filled with old and recent clot up to this point.

CASE B.—G. T., male, aged 39 (9/9/19). No cardiac symptoms, sudden cerebral hæmorrhage; recent ischæmic necrosis of anterior wall of left ventricle.

A history of a weak heart, but he was working regularly, and apparently in his usual health. He suddenly dropped down unconscious, and was admitted into hospital with a hemiplegia and in coma. He died a few hours afterwards.

Post-mortem examination showed a ruptured aneurysm of the left middle cerebral artery, a small grey tumour close to the septum lucidum on the left side, congenital cystic kidneys with a tuberculous mass in one, tubercle of lungs and the heart. This was slightly enlarged chiefly on the left side, with a very early softening involving a large area of the anterior wall of the left ventricle. No cause for this was apparent. There was only slight atheroma of the aorta and the large vessels in the abdomen. Another unruptured aneurysm in the anterior communicating vessels in the circle of Willis.

CASE C.—R. A., male (11/8/15). Chronic cardiac failure; area of extreme fibrosis in anterior wall of left ventricle related to a branch of right coronary artery.

In good health till the December preceding admission. He then became short of breath and his feet became swollen. Admitted with great dyspnœa and œdema. Pulse 120, of poor quality and irregular. Cardiac sounds were distant but probably pure. Ascites and pleural fluid. Albuminuria marked.

Post-mortem.—A large heart, the right ventricle being markedly hypertrophied. There was a large area of extreme fibrosis of the front of the left ventricle with great thinning of the area from which the papillary muscles sprung, with marked atrophy of the papillary muscles. This was related to extreme patchy atheroma of the *right* coronary artery. The aorta was almost completely free from atheroma save around the orifice of the coronary arteries. Valves normal. Subacute parenchymatous nephritis.

CASE D.—J. H., aged 63 (27/7/13). Sudden, followed by chronic, cardiac failure; infarction of lower two-thirds of left ventricle; local adherence of pericardium, occlusion of left coronary.

On June 5th, 1913, when climbing up a gangway into a ship he suddenly became very breathless and had to stop. His fellow workmen pulled him up to the deck and he soon felt better, but he went home and stayed in the house for four days. As he then felt quite well he resumed his work, but at once became short of breath and was only able to continue at work for a couple of days. He went to bed, as his feet and legs were now swollen. The breathlessness became worse and he had to sit up in bed. He was restless and slept but little. A few days later he began to experience pain in the region of the heart, and all his symptoms increased in severity. On June 25th he spat up a considerable amount of blood, and the hæmoptysis continued.

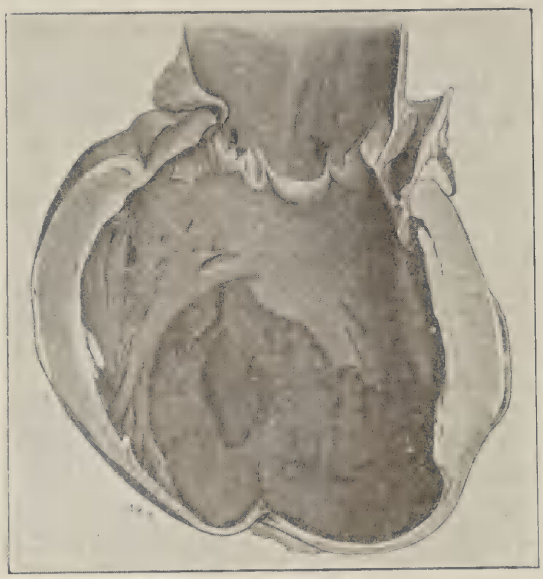
[3] Ibid.



Case D.—Aneurysmal dilatation of left ventricle involving septum and posterior wall.

On admission he was collapsed, cyanosed and cold, and semi-conscious with shallow breathing which came in gasps. His pulse, 75, was regular and of moderate pressure. Next morning he was rather better, but the extremities were still blue and cold. The breathing was regular and more full but noisy. Pulse 60, small, and of moderate pressure. Apex in fifth space underneath the nipple. Cardiac sounds distant and indistinct. Œdema extended on to the trunk. Liver enlarged and tender. Dullness and râles at the bases. Emphysema. Next day he had rallied to some extent, but he was still very breathless and the hæmoptysis continued. No notable change occurred, but on July 7th he was rather restless and died suddenly.

Post-mortem (see figure).—The lower two-thirds of the left ventricle was softened from an infarction, the edges of which were pale. At the leftmost part of the apex the wall was only about $\frac{1}{8}$ in. thick, but there was no perforation. The area involved bulged slightly, and the pericardium was adherent, with fibrinous exudate at the edges. Valves normal. Slight superficial atheroma in patches on the aorta. The left coronary artery was occluded by a dense, thick, atheromatous patch $\frac{3}{4}$ in. in extent, situated about 1 in. from the orifice and extending down to the infarct.

Case E.—W. B., male, aged 61 (31/5/21–9/6/21). Angina pectoris. Numerous small infarcts in lower two-thirds of left ventricle, including septum. Syphilitic aortitis.

His illness commenced about the spring of 1917, when he first began to experience pain in his chest when on the way to work in the morning. It had usually ceased when he started work and he paid little attention to it, as he thought that it was due to indigestion. In September, 1917, it became more acute, and he had to seek admission into hospital. The pain at first was situated low down in the chest, but subsequently extended upwards and into the left armpit and left arm. At first the attacks were of short duration, a minute or two, but they were so severe that he had to stop dead until they passed away. In February,

CLINICAL TYPES OF ISCHÆMIC NECROSIS.

Sudden Death.

No.	Author and reference.	Sex.	Age.	Symptoms.	Heart.
1	Fagge.[1]	M.	85	Sudden death.	Fibroid apex and anterior part of septum.
2	Do.	M.	61	Dyspnœa, giddiness. Sudden death.	Fibrosis of field of anterior branch of left coronary. Local dilatation.
3	Hale-White.[2]	M.	40	Sudden death.	Large fibrous mass in posterior wall of ventricle.
4	Do.	M.	43	Large heart. Sudden death.	Septum of ventricles white and fibrous.
5	Do.	M.	—	Dilated heart. Sudden death.	Apical half of left ventricle fibrous; also elsewhere.
6	Butlin.[3]	—	—	Sudden death.	Fibrous patch of interventricular septum; thrombosis of brachial, hepatic and superior mesenteric arteries; gangrene of duodenum.
7	Green.[4]	M.	52	Sudden death.	Fibrosis of interventricular septum.
				Angina.	
8	Herrick.[5]	M.	55	Pain in lower chest; vomiting; rapid heart failure; lived 52 hours.	Thrombosis of descending branch of left coronary.
9	Do.	M.	65	Præcordial pain; falling B P. Later dyspnœa and dropsy; lived 2 weeks.	Thrombus of descending branch of left coronary.
10	Do.	M.	42	Sudden violent pain lower sternal region, arms, and epigastrium. Collapse. About again in 10 days. Dyspnœa and cyanosis. Sudden death.	Area of descending branch of left coronary fibrosed, and descending branch of left circumflex.
11	Peacock.[6]	M.	60–70	Dyspnœa and substernal pain some weeks.	Fibrosis of anterior wall of left ventricle more marked below.
12	Obrastzow and Straschesko.[7]	M.	49	Substernal pain, cyanosis, feeble heart. Sudden pain sternum, neck, and head.	Thrombosis of left coronary.
13	Do.	M.	57	Substernal pain, cyanosis, Cheyne-Stokes breathing.	Thrombosis of left coronary.
14	Do.	M.	57	Substernal pain and down left arm, Cheyne-Stokes breathing.	Thrombosis of left coronary.
15	S. West.[8]	—	40	Extreme spasmodic pain in præcordium.	Fibrosis of base of left ventricle.
16	Mackenzie.[9]	F.	57	Increasing pain in chest, at first paroxysmal: slight breathlessness might precede pain.	Ischæmic necrosis and fibrosis in field of descending branch of left coronary.
17	Do. Case 2.	M.	64	Angina of effort. Breathlessness. Sudden death.	Ischæmic necrosis in field of septal branch of anterior branch of left coronary artery.
18	Do. Case 4.	F.	60	Angina of effort. Pain in left forearm.	Fibrous changes in muscle of left ventricle; calcification of coronary arteries.
19	Do. Case 6.	M.	48	Angina of effort. Pain chest, neck, and jaw —sometimes arm.	Small aneurysm of left ventricle. Rupture of heart.
20	Do. Case 7.	M.	52	Breathlessness on walking and pain in stomach.	Aneurysmal dilatation of right ventricle containing clot.
21	Do. Case 10.	M.	46	Shortness of breath 2 years and pain 1 year before death on walking. Pulsus alternans 1 week before death.	Fibrosis in field of anterior branch of left coronary artery.
22	Do. Case 11.	M.	48	Pain in præcordium and left arm, with breathlessness brought on by effort. Irregular rhythm.	Fibrosis in field and obliteration of anterior branch of left coronary artery, septum, and left ventricular wall.
23	Do. Case 21.	M.	57	Weakness and breathlessness on exertion. Later attacks of angina. Pulsus alternans.	Apical half of left ventricle dilated and fibrosed.

1918, he was able to resume work, at which he continued till April, 1921, when the pain became more severe and more constant, preventing him from sleeping, and even awakening him from sleep at times.

The pain at the time of admission was dull and heavy, and commenced in the axilla and shot inwards to the lower end of the sternum. At first the pain commenced in the thorax and spread to the arm. An attack might last for three hours. It did not invariably involve the arm. The attacks occurred every day and even several times in the day. During his residence many attacks were observed. His breathing became frequent, and he became restless and sat up in bed, with his shoulders bent forwards. The pain did not appear to be very severe. During these attacks the abdomen was always distended and tight, and relief followed the movement of the bowels or the passage of flatus. We formed the impression that the attacks were abdominal in origin though he said that the pain was thoracic. He was not talkative during these attacks, but sighed frequently and perspired freely. Well-marked paralysis agitans. A mitral systolic murmur was present and a diastolic aortic murmur. Blood pressure 145–60 mm. Hg. Temporal, brachial, left facial, dorsalis pedis, femoral arteries were all palpable and tortuous. Retinal arteries narrowed and thickened. There was some œdema. After admission the attacks continued. On June 7th his temperature rose to 101° F., the pulse to 100, and the respirations to 32. He was sick on several occasions. *The pain at this time was constant*, and his general condition rapidly deteriorated. He died from cardiac failure.

Port-mortem examination showed numerous small infarcts over lower two-thirds of left ventricle and adjacent septum. Recent pericarditis. Advanced syphilitic aortitis, nipping the orifice of the left coronary artery, the lumen of which was obstructed a few millimetres below. The branches showed gross lesions. The right artery was pervious though notably atheromatous. The renal and mesenteric arteries showed numerous thickened patches, and the kidneys many arterio-sclerotic scars. Mitral valve normal; aortic thickened.

A very instructive case. The diagnosis of angina seemed clear and its gastro-intestinal origin, but the patient's neurotic tendencies and his excessive complaints made the real question difficult to solve. The appearance of *constant* pain and friction made the whole thing clear.

CASE F.—Mrs. B., aged 45 (30/1/22–8/2/22). Acute abdominal symptoms with collapse, localised infarct of left ventricle with ball thrombus.

Admitted on account of severe pain in the abdomen on the left side with collapse. Multipara. Her last baby was born

CLINICAL TYPES OF ISCHÆMIC NECROSIS—(*Continued*).

Chronic Heart Failure.

No.	Author and reference.	Sex.	Age.	Symptoms.	Heart.
24	Fagge.[10]	M.	69	Dyspnœa and dropsy for 7 weeks.	Posterior wall of left ventricle very thin; replaced by fibrous tissue.
25	Do.	M.	42	Dyspnœa and dropsy; rheumatic fever 19 years previous.	Posterior wall of left ventricle completely fibrous.
26	Do.	M.	43	Dyspnœa 2 months after cholera; dropsy 10 months after. Death 14 days after onset of dropsy. Sudden death.	Septum and adjacent anterior parts of left and right ventricles converted into fibrous tissue.
27	Writer's observation.	M.	49	Dyspnœa 5 months. Dropsy 1 month; fibrillation.	Fibrosis of tip of left ventricle and recent ischæmic necrosis of posterior papillary muscle.
28	Bristowe.[11]	F.	39	Dyspnœa and some dropsy; irregular pulse.	Extensive fibrosis lower anterior portion of heart including part of septum.
29	Mackenzie.[12]	M.	72	Hemiplegia followed by hæmaturia, shortness of breath, pulsus alternans, cardiac asthma, dropsy.	Intense fibrosis, with ante-mortem clot internally, at apex of left ventricle.

Abdominal Symptoms and Collapse.

No.	Author and reference.	Sex.	Age.	Symptoms.	Heart.
30	Writer's observation.	M.	64	Abdominal pain and vomiting 5 days, followed by 2 days of absolute constipation.	Old fibrosis in area of anterior branch of left coronary; embolism of superior mesenteric artery.
31	Writer's observation.	M.	46	Angina of effort some months; 24 hours diarrhœa, vomiting, and collapse.	Fibrosis of field of anterior branch of left coronary artery, calcification and occlusion.
32	Samuelson.[13]	M.	47	Diarrhœa, vomiting, and collapse. Pulse 35.	Sclerotic narrowing of both coronaries.
33	Hammers.[14]	—	—	Collapse. Pulse 40.	Right coronary thrombosed.
34	Gallavardin et Dufont.[15]	—	—	Collapse. Very slow pulse.	Embolism of coronary artery.
35	Faulkner, Marble, and White.[16]	M.	60	Repeated attacks of severe pain upper abdomen.	Occlusion of a branch of descending left coronary artery with infarct of left ventricular wall.
36	Do.	F.	55	Severe pain in right lower chest and right upper abdomen. Operation for gallstones proposed.	Occlusion of right coronary artery and partial of descending branch of left.
37	Hardt.[17]	M.	66	Pain lower chest, intermittent nausea, and vomiting followed by fibrillation.	Old thrombosis of left coronary artery with myomalacia cordis, aneurysm, and mural thrombosis.

Fainting Attacks.

No.	Author and reference.	Sex.	Age.	Symptoms.	Heart.
38	Writer's observation.	M.	72	Fainting attacks at rare intervals, one with collapse and irregular pulse. Sudden death.	Old fibrosis in field of right coronary artery. Recent ischæmic necrosis of septum, also in field of right coronary artery.

Delirium and Failing Pulse.

No.	Author and reference.	Sex.	Age.	Symptoms.	Heart.
39	Writer's observation.	M.	83	Sudden delirium; dyspnœa, failing pulse. Three days' illness.	Obliteration of anterior branch of left coronary.

No Cardiac Symptoms.

No.	Author and reference.	Sex.	Age.	Symptoms.	Heart.
40	Fagge.[18]	M.	66	No cardiac symptoms. Renal cancer.	Fibrosis of posterior wall of heart.
41	Do.	M.	55	No cardiac symptoms. Gangrene of foot; gradual asthenia.	Fibrosis of posterior wall of left ventricle. Local pericarditis over softening.
42	Writer's observation.	M.	76	Had undergone prostatectomy 3 weeks before death from strangulated hernia.	Healed patch of fibrosis near apex of left ventricle; anterior branch of left coronary was completely obstructed.
43	Writer's observation.	M.	—	Carcinoma of rectum. Colostomy. Sudden death.	Calcification of both coronaries; ischæmic necrosis of left ventricular tip; aneurysmal dilatation rupture into pericardium.

eight months before, and since then she had had symptoms of renal and cardiac disease. General œdema, &c., bronchitis, emphysema. Cardiac sounds pure but weak and distant. Steady deterioration. Infarct of lungs on Feb. 4th.

Post-mortem. — Hypertrophy and dilatation of left ventricle. A ball-shaped clot at the apex probably related to a myocardial infarct which, however, did not extend through the whole depth of the muscle. Right heart much dilated, with clots in auricle. Infarcts in spleen and lungs. Interstitial nephritis. Thoracic aorta was fairly normal, but the abdominal aorta and the splenic artery were grossly diseased. The valves were very slightly thickened.

CASE G. — Mrs. F., aged 65 (24/10/07–27/10/07). Gradual cardiac failure; obliteration of right coronary artery, aneurysm of posterior wall of left ventricle.

A history of palpitation for some years. Œdema of the feet occurring about 12 months before admission, with shortness of breath, and becoming marked three weeks before admission. The œdema became excessive and the legs burst, with numerous small sores on the left leg which had become septic.

On admission anasarca marked, with great dyspnœa and cyanosis. Slightly delirious. Albumin abundant. A mitral murmur was present, and the pulse was irregular. On Oct. 27th, 1907, the patient died in a sudden syncope.

Post-mortem examination showed a large heart weighing 23 oz. The main branch of the right coronary artery was practically obliterated, and an aneurysm had formed on the posterior wall of the left ventricle about the junction of the upper and middle third. The wall was fibrosed, and no muscle cells were visible to the naked eye on section. The endocardium was much thickened. The aortic valves were thickened, with an acute endocarditis superimposed. The mitral was thickened The splenic and renal arteries were sclerosed. Interstitial nephritis. The acute endocarditis was probably secondary to the sepsis in the legs.

CASE H.—J. M., male, aged 62 (30/9/24–2/10/24). Gradual cardiac failure; diffuse early fibrosis of myocardium.

About 18 months before admission he began to feel short of breath and unfit, and had to give up his work. On July 24th his feet became swollen. On Sept. 30th, 1924, he collapsed with Cheyne-Stokes breathing. The heart was large with a mitral systolic murmur and distant poor sounds elsewhere. Pulse about 100, regular, and of fair volume, with blood pressure 147 max., 100 min. The chest was practically clear. No improvement ensued and he died suddenly.

Post-mortem examination showed a large heart, 32 oz., with a few patches of old pericarditis on the surface. The aortic valves were slightly thickened. The other valves were normal. The myocardium showed diffuse early fibrosis, the aorta and the coronary arteries showing arterio-sclerotic changes.

Prof. F. R. Fraser's Cases.

CASE I.—W. C., aged 65 (7/7/24–7/9/24). Abdominal angina; ischæmic necrosis of a large portion of the left ventricle and a portion of the right.

History.—Increasing shortness of breath for preceding two years. Attack of dyspepsia three months previously. On morning of July 5th woke up with acute pain in epigastrium and upper abdomen. Very short of breath, increasing cough and cyanosis. During the 6th pain and dyspnœa increasing and restlessness marked.

On examination: A short, stout man, cyanosed and in pain, giving a muddy complexion, very great difficulty in breathing. Temperature 98·6° F., pulse 130, respirations 40. Thorax moving very poorly and jerkily; air entry poor, breath sounds vesicular with prolonged expiration; rhonchi, sibili, and râles at both bases, especially right. Position and size of heart could not be made out with any accuracy because of emphysema and the noisy respiration. Heart sounds judged to be both very feeble. No irregularity. No œdema of subcutaneous tissues. Abdomen distended but moving well, no localised rigidity or tenderness. Liver enlarged, edge felt 2 in. below costal margin. Urine: Sp. gr. 1026, trace of albumin and of acetone. Nervous system: Nothing abnormal found except that left ankle-jerk could not be elicited.

July 8th: In early morning noticed to be not moving right arm and right leg, and on examination it was found that there was a weakness of right face also. The arm-jerks were present and equal; the right knee-jerk and right ankle-jerk were brisker than the left, and the plantar response on the right was extensor. No improvement occurred with administration of oxygen. Morphine and adrenalin were given hypodermically without improvement. Temperature rose to 100·8°, pulse 160, and death occurred in morning of the 9th.

Post-mortem Examination. — Lungs congested and œdematous. Gastric ulcer, chronic, 2 in. above pylorus. Embolus of branch of left middle cerebral artery and subcortical area of softening. Cardio-vascular system: A small amount of turbid fluid was present in the pericardium, and some recent lymph present on anterior surface of heart. Subpericardial hæmorrhage over the left auricle. Right auricle considerably dilated and hypertrophied. Tricuspid orifice admitted four fingers. Valve was slightly opaque and a hæmorrhage present on anterior cusp. Left auricle hypertrophied. Mitral orifice admitted three fingers, valve thickened, but no stenosis. Left ventricle markedly dilated and somewhat hypertrophied. Pulmonary veins appeared normal. Aortic valve somewhat thickened, and ascending part of aorta showed some fatty changes. Remainder of thoracic aorta was involved extensively in an ulcerative atheroma. Coronary arteries thickened and the posterior interventricular branch was filled with an embolus. Musculature of the left ventricle almost entirely involved in acute softening, with the presence of small hæmorrhages into the substance of the muscle. On the inner surface the appearance was of a yellowish necrotic change. A considerable but much smaller portion of right ventricle showed the same change.

Histological Examination by Sir Bernard Spilsbury.—Heart muscle teased in osmic acid—large irregular deposits blackened with osmic acid in most of the muscle cells. These deposits resemble lipoids developing in putrefaction. They are probably due to myomalacia. Ordinary preparations show numerous areas of recent myomalacia scattered throughout the myocardium. In these areas the muscle cells have partly lost their nuclear staining properties, but the cells are not distinguished. These areas are markedly infiltrated by polynuclear cells, and in some parts there are also hæmorrhages. The endocardium over these areas is infiltrated with polynuclear cells, and thrombi adhere to the inner surface of the heart. The thrombi are laminated, the laminæ being chiefly fibrinous with layers of red clot; some of the laminæ are markedly infiltrated with polynuclear cells. There is also some polynuclear cell infiltration of the epicardial fat adjacent to areas of myomalacia, and there are hæmorrhages in this tissue. No organisms seen. No changes in blood-vessels of heart to account for myomalacia.

Dr. K. D. Wilkinson's Cases.

CASE J.—A. C., aged 50 (3/11/24–6/11/24), under Dr. W. H. Wynn. Angina pectoris, occlusion of left coronary, infarction of left ventricle.

He was admitted complaining of burning stabbing over præcordium. He had severe attack of angina on admission. Accentuated second sound aortic area. Apex beat sixth space, 4 in. from mid-line. Friction rub heard over left lower lobe anteriorly, probably pleural in origin. Pain radiated but little and was confined to præcordium. He was an elderly, powerfully-built man of the ruddy type, obviously older than his years, but at a first glance did not look very ill. He was sitting in a chair, leaning slightly forward, and rather pale. A closer inspection showed that he was slightly cyanotic. The striking thing about him was his immobility; he would hardly move a limb, and in talking spoke very quietly and slowly. He moved his eyes rather than his head.

He said that he had had attacks of præcordial pain for some months, but these had never been very severe, and had always passed off pretty soon; but this attack had come on two days previously and had remained severe ever since the beginning. There were times when the pain was easier, and times when it was of the greatest intensity, but it was so bad all the time that he was unwilling to talk, dared not move, and had hardly had anything to eat since it began. Amyl nitrite hardly had any effect in the out-patient room, and during the three days he lived after admission he had a great deal of pain and died in an exacerbation. Morphine seemed the most effective drug, but was never able to abolish the pain. The pulse was steady, rather slow, poor in volume, and the vessel wall was thickened. There was no palpable pressure abnormality (he was obviously too ill for the pressure bag).

Post-mortem.—A muscular well-nourished body. Pericardial sac: Adhesions, old standing, were present towards the base of the heart and at the apex of the right ventricle. The præcordium covering the front of the right ventricle was thickened and opaque.

A delicate layer of recent fibrinous exudate covered practically the whole of the left ventricle. The left ventricle was somewhat dilated. There was a large mass of pale thrombus entangled amongst the columnæ carneæ at the apex. Practically the whole of the lower two-thirds of the left ventricle was infarcted, the muscle having a dull, opaque, greyish-white appearance with irregular areas of congestion. The aortic valve segments were slightly thickened and there was a delicate layer of recent thrombus along the lines of contact of the cusps. The first part of the aorta was considerably dilated and showed an extreme degree of atheromatous thickening and was narrowed to an extreme degree, so that it only admitted the point of a dissecting needle. A small plug of pale thrombus completely occluded this greatly narrowed orifice. The artery itself showed only a few patches of atheroma. No gross lesion was found in the auricles or right ventricle. The dilatation of the aorta extended as far as the beginning of the descending portion, and in addition to the atheromatous changes described there were many areas of pearly white thickening of the intima and scarring of the endothelium, the appearances being those of a syphilitic mesaortitis. The rest of the aorta showed irregular patches of atheroma. Both lungs showed hypostatic congestion and extreme generalised œdema. Peritoneum: normal. Liver: 2200 g.; showed early chronic venous congestion and some fatty infiltration. Spleen: 125 g.; rather atrophied, and the pulp was distinctly fibrous. Kidneys: 430 g.; showed some recent œdema and congestion; the vessels were somewhat thickened.

CASE K.—W. G., aged 61 (7/6/25–11/6/25), under Dr. L. G. Parsons. Acute attacks of collapse, angina. Thrombosis of the main trunk of the left coronary. Infarction of the apical portion of the left ventricle. Pneumonia—right apex. Chronic venous congestion of all organs.

The illness began with a sudden sharp attack of collapse, but he did not lose consciousness; was breathless. There were previous attacks many years ago. No recent illnesses. Bowels free. He was admitted cyanosed, pulse-rate 62, poor in volume. Pain at left base anteriorly, pleuritic rub at right base posteriorly. Otherwise no physical signs. On June 10th, 1925, the patient had an attack of palpitation with a feeling of suffocation. Diagnosis: Angina pectoris.

Post-mortem.—The body was that of a well-built, elderly man. The lungs were prominent, due to hypertrophic emphysema. To a large extent they obscured the cardiac area. The peritoneal cavity was normal. Heart (500 g.) and pericardium. On opening the pericardium a little turbid fluid was seen, and fibrinous adhesions attached the pericardium to the apex and anterior aspect of the left ventricle. These were easily broken down, and the heart muscle underneath them was very firm in consistence and presented a mottled appearance of infarction. On opening the left ventricle (which was hypertrophied and dilated), the area of infarction could be distinctly seen extending right through the heart muscle, and to the internal surface of this area a quantity of antemortem thrombus was adherent. The interventricular septum did not appear involved in the infarction, although it was of wide extent, involving the whole of the apical portion of the heart. Some areas of the infarct showed the condition of "myomalacia cordis." There was some fibrosis of the papillary muscles. The left coronary, which showed advanced atheroma with much narrowing of its lumen, contained a mass of thrombus about 1½ in. from its origin. This was formed upon a calcified patch. The right coronary was very atheromatous but was not thrombosed. The orifices of the coronaries were somewhat narrow. The aorta was very atheromatous. The orifices of the intercostals were narrowed and there were two patches of atheromatous ulceration, over one of which the intima had given way completely so as to produce a commencing dissecting aneurysm. Lungs: Left upper lobe was consolidated and completely airless. The left base was œdematous. Right: Upper lobe partly consolidated. Liver: 1700 g.; chronic venous congestion. Kidneys: 380 g.; chronic venous congestion. Spleen: 160 g.; chronic venous congestion. Radial artery was almost normal in appearance and the vessels of the kidneys were the same.

NATIONAL MEMORIAL TO QUEEN ALEXANDRA.—This memorial is, with the sanction of the King and Queen, to take the form of an augmentation of the resources of Queen Victoria's Jubilee Institute for Nurses, of which Queen Alexandra was the patron. Under the charter of the Institute the Queen succeeds to that position. All the affiliated nursing institutions will be given the opportunity of participating, and the Long Service Fund for England Irish and Wales will benefit. It is hoped, moreover, that the and Scottish organisations will be able to proceed on similar lines. Over 1200 associations are affiliated to the Institute.

THE NEW WHITEHAVEN INFIRMARY.—Some four years ago Whitehaven Castle, the Cumberland residence of Lord Lonsdale, was purchased and presented by an anonymous donor, together with £20,000, for conversion into a new Whitehaven and West Cumberland Infirmary. The alterations have now been completed. The ground floor, consisting of a long range of low rooms, is used for administrative purposes, the dispensary, X ray, electrical, out-patients' and casualty departments. The first floor has been turned into wards for men, women, and children, and the total accommodation is 86 beds—there were formerly 60—with 47 staff bedrooms.

LUPUS OF THE NOSE AND UPPER AIR PASSAGES TREATED BY RADIUM.

BY H. MORTIMER WHARRY, F.R.C.S. ENG.,
LARYNGOLOGIST TO THE WEST END HOSPITAL FOR NERVOUS DISEASES, AND ASSISTANT AURAL SURGEON TO THE BOLINGBROKE HOSPITAL; ASSISTANT TO THE THROAT AND EAR DEPARTMENT OF UNIVERSITY COLLEGE HOSPITAL, LONDON;

AND

OSKAR TEICHMAN, *D.S.O.*, *M.C.*, M.R.C.S. ENG.,
ASSISTANT MEDICAL DIRECTOR TO THE RADIUM INSTITUTE, LONDON.

Ætiology.

LUPUS, contrary to the usual belief, is a disease that affects the mucous lining of the nose, mouth, and upper air passages quite as much as the skin of the face and neck. In fact, in almost all cases the granulations start in the nose at the junction of the skin of the vestibule with the mucous membrane, or just on the mucous side of that junction, and spread to the skin of the face, as well as the inside of the nose.

Lupus affects young adults of both sexes, and in our experience male sufferers are as numerous as female; but this is not the opinion of some authorities. It is not often seen before the age of 15, and, in its active stage, rarely above the age of 40, though the disfigurement caused by its ravages lasts until the death of the patient. By far the greater number of cases are about the age of 20, and of the lower middle class.

Pathology.

Lupus is caused by a mild form of tubercle bacillus and spreads very slowly. On the skin the lesions are of the "apple-jelly nodule" type, with peripheral spread. As the disease makes headway there is ulceration just within the periphery of its area, while in the centre scarring takes place spontaneously. The scarring is of a rough and very disfiguring nature, with irregular contractions of the white scar tissue, and red patches between.

Several types are recognised by skin specialists. In the upper air passages four definite macroscopical types are recognisable.

(*a*) *Granulations.*—This is the most common and most typical form. The granulations are often spread evenly over the surface of the mucous membrane, and may extend from the vestibule of the nose as far as, and even to a little below, the larynx. They are soft and velvety in appearance and to the touch; and have occasionally a greyish surface, which bleeds on touching with a probe or other instrument.

(*b*) *Vegetations or Proliferations.*—These occur, as a rule, only in the vestibule of the nose, and resemble a branching sessile papilloma. They may protrude at the nostril. They occur in conjunction with other types of the disease in the same patient.

(*c*) *Tumours.*—It is difficult to explain the formation of these lumps or to say of what they consist. They occur in the choanæ and on the superior surface of the soft palate, and can be seen with a post-nasal mirror. They have no connexion with the posterior ends of the turbinated bones. They are also found in the interarytenoid region of the larynx, and cause obstruction to the vocal processes of the arytenoid cartilages, preventing full approximation of the vocal cords. They must not be confused with tuberculous tumours or pachydermia of this region. They disappear on the application of radium.

(*d*) *Ulceration.*—This is a very troublesome variety, which is found most commonly in the mouth, on the under surface of the lip, and on the hard and soft palate. It is very resistant to all forms of treatment, and consists of a heaped-up and thickened mucous membrane, in which are small, deep, punched-out serpiginous ulcers or pits. This form of the disease bears a superficial resemblance to some forms of syphilis and is often mistaken for it.

Reaction of the Four Types Described to Radium Treatment.—Of the types of lupus described, the first three may be considered to be particularly favourable in their yielding to treatment by radium. These three types are: (*a*) Granulations, (*b*) vegetations, and (*c*) tumour formation. The last type (*d*) ulceration is much less readily dealt with, but can be arrested and held in check in a satisfactory manner. As will be seen later, where the action of radium is described, the reason for this less favourable reaction to treatment is most probably due to the fact that less granulation tissue is formed in this type of the disease than in the others.

Modes of Spread.

Starting in the Nose.—Although the following modes of spread are described separately they may be found in conjunction with one another. The granulations may start just inside the nose, at the junction of the skin of the vestibule with the mucous membrane, and may be found either on the septum, the inside of either of the alæ nasi, or on the floor of the nasal fossæ. From this starting point they may spread in three directions: (1) To the outside of the nose, with apple-jelly nodules on the skin, and ulceration and gradual destruction of the alæ nasi. This is accompanied by much thickening of the structures of the nose, both cartilaginous and soft; and the vestibule is blocked and often widely stretched by masses of hard crusts, which can be picked off, leaving a bleeding surface, but which re-form again in a very short time. This type leaves behind it the facial disfigurement with which everyone is familiar, and which is very unsightly and distressing to a female patient. Once having reached the skin, the disease may spread widely over the face if not checked by suitable treatment. (2) Along the nasal fossæ to the rest of the upper air passages. The common mode of spread is along the inferior turbinated bone, but the septum may be affected and even perforated. The posterior ends of both inferior and middle turbinates may be covered with granulations. The superior surface of the soft palate is next affected, and tumours may form in this position where they rest against and are attached to the vomerine part of the nasal septum. The whole post-nasal space may be covered, including the Eustachian cushions and posterior pharyngeal wall. From the superior or naso-pharyngeal surface of the soft palate the disease spreads over the uvula and buccal surface, and so on to the hard palate. Tracking down the anterior and posterior pillars of the fauces and over the tonsils or tonsil beds, it then gains the epiglottis and eventually covers the whole of the larynx. The epiglottis becomes swollen, covered with granulations, and eventually either permanently thickened or else eaten away. The vocal cords are often completely covered, with loss of voice, which may be permanent if not rightly treated. Tumours may form in the interarytenoid region. In addition to the larynx the posterior third of the tongue may be invaded, with much heaping up of granulations, and stiffness and soreness of the organ itself. (3) Starting in the floor of the vestibule, the disease may track through into the angle between the lip and the alveolus of the upper jaw, and so gain the buccal cavity, where it spreads along the gums and on to the hard and soft palate.

Starting on the Lip or Gums.—The granulations may first appear on the lip and spread over the gums and hard and soft palate and so to the pharynx and larynx. Or they may miss the palate altogether, and leap straight from the lip to the pharynx or larynx.

Clinical Manifestations.

The chief thing noticeable about these patients is that though they may be suffering from a very extensive lesion, they are not definitely ill; although they are usually in a poor state of health, and are found on questioning to live an indoor life under conditions which are not conducive to general physical fitness. Apart from this the symptoms of the disease are those which it produces according to the actual organ affected.

(1) *In the Nose.*—Nasal obstruction is produced by granulations or proliferations of the papillomatous type on the anterior part of the septum and the inner surfaces of the opposing alæ nasi. The obstruction invariably persists, and is maintained later by the thickening of the soft parts, and the piling up of granulations and thick crusts, which form so unpleasant a feature of the disease. This obstruction often lasts for years and may be permanent if unwisely treated. Nasal discharge is one of the earliest signs. It is very scanty and thin, sometimes tinged with blood, and arises from the granulations. It rarely persists for more than a year, after which the nose becomes dry. Bleeding is not common, but occurs from the granulating surface when a crust is removed. It is not profuse.

(2) *In the Post-nasal Space.*—The condition here is one of dryness and scarring which spreads down the posterior pharyngeal wall. There may also be nasal obstruction made more pronounced by the formation of tumours in the posterior choanæ.

(3) *Soft Palate and Fauces.*—Both surfaces of the soft palate and all the pillars of the fauces are frequently attacked together. The result is a thickening, stiffening, and immobility of these parts, occasioned not only by the active disease itself, but by the scarring left by it, when eventually, after the passage of years, it becomes healed. This condition leads to a nasal intonation of the voice, and, on rare occasions, to regurgitation of fluids into the nose when swallowing.

(4) *Mouth and Tongue.*—There is thickening, stiffness, and deformity of the lips where they are affected, and a general dryness and soreness of the mouth, especially where there is widespread thickening of the mucous membrane with the deep, indolent, serpiginous ulceration already described. The tongue may be rendered slightly immobile and the taste impaired.

(5) *Larynx.*—The most serious effects are seen in this part. Huskiness is a common symptom when the epiglottis and parts of one or both vocal cords or the interarytenoid region are affected. But the disease soon overwhelms the whole larynx with total loss of voice, which persists for many years, and may be permanent if allowed to progress until the larynx becomes a mass of scar tissue, or if it is unwisely treated. In such cases, not only is the voice irretrievably lost, but the glottis sometimes becomes inadequate, and tracheotomy has to be performed, a result which can only be described as disastrous. When there is loss of voice the whisper is often very feeble owing to the larynx becoming stiff, and being held widely and rigidly open, so that a forcible stream of air cannot be expelled through it, as through a narrower orifice. The result is that the whispered speech can only be heard by placing the ear close to the patient's mouth.

Prognosis.

Considerable divergence of opinion in certain details is to be observed among authorities of long experience. In certain favourable cases there is a definite tendency to heal under conditions which, as is aimed at in frank tuberculosis, promote the general health and resistance. On the other hand, in the great majority of patients the disease goes on for many years, and eventually leaves its victim hideously disfigured, with permanent nasal obstruction, permanent loss of voice, and sometimes even with a tracheotomy.

While Sir StClair Thomson in England emphasises this tendency to heal, in America Wendel Christopher Phillips in his standard text-book dismisses the subject in the following words: "Laryngeal lupus is practically never cured. It may be arrested for a time, but it will finally reappear and cause a fatal termination." The authors' own experience is that in the majority of cases a definite disappearance of the disease can be obtained by suitable measures of treatment; and that if in certain small areas there is a tendency to recur, the local recurrence can again be dealt with by a repetition of the same treatment. Even in those cases of the "ulcerative" type, which most obstinately resist treatment, a great mitigation and relief of symptoms can be obtained within a short time.

Treatment.

(1) *General.*—All possible means must be taken to improve the general health—i.e., an open-air life, a generous diet, and tonics containing iron and arsenic, or cod-liver oil and malt.

(2) *Local.*—The unsatisfactory nature of previous methods of local treatment can be estimated by their large number, and by the fact that only one method has any enthusiastic adherents. This method is the destruction of the disease by galvano-cautery. But even this is not applicable to cases where the disease is very extensive and, as may readily be understood, to a large extent inaccessible to its application; as, for example, when the seat of the disease is the post-nasal space. The authors can recommend the following methods of treatment:—

In Slight Cases.—When the disease is in the neighbourhood of the vestibule of the nose, or in parts of the mouth which are readily accessible, the galvano-cautery is a rapid and easy method of exterminating very small patches. The burning causes replacement of the affected area by strong white scar tissue, which has, however, the effect of immobilising the part so treated.

In Severe and Extensive Cases.—In the authors' experience the majority of cases, when first seen, have reached a stage which puts them in this category, for which they can confidently recommend treatment by radium.

Clinical Aspect: The Present Situation of Radium Therapy for Lupus of the Upper Air Passages.

(*a*) This method of treatment, as is mentioned later, is not new. But very few cases have previously been published, and so its advantages have not come into prominence. But, having closely observed the progress of a series of fresh cases for a period extending over two years, the authors feel that the results have been so happy that further delay in publishing them is unnecessary. They realise that time alone can give the ultimate scientific verdict on the questions of complete cure and possible recurrence. But during the years that must elapse before such a verdict can be given many sufferers might be condemned to years of speechlessness and a lifetime of disfigurement which could quite well be avoided. The authors are convinced that the aphonia is in the majority of cases curable and the facial disfigurement avoidable. They would therefore urge that the disease should be treated before it has exceeded the limits which allow of a satisfactory result being obtained—i.e., before the larynx has been partially destroyed and before facial disfigurement has actually occurred.

Further experience in radium therapy of lupus of the upper air passages is necessary to enable an authoritative announcement to be made; but it may reasonably be hoped that, in dealing with the obstinate ulcerative type of lupus, a method of reducing it more rapidly may soon be found.

(*b*) *Coöperation between Laryngologist and Radio-therapeutist.*—This ensures the correct dosage of radium being given and also its accurate application to the affected area. We regard this as the fundamental condition of success in treatment, and feel justified in doing so because of satisfactory results which have attended this collaboration. The laryngologist should always point out the particular parts requiring radium applications, and when necessary should manipulate the tubes into position and apply cocaine as occasion requires. This is especially necessary deep in the nose, the post-nasal space, and on the soft palate.

(*c*) *Advantages of Treatment by Radium.*—In addition to the successful alleviation of the complaint this treatment has much to recommend it. The treatment consists of short courses of four to five hours on three, four, or five consecutive days. These short courses are repeated at intervals of six weeks to two months, for a year or even longer until the disease is eliminated. At each session the tubes or plates are placed in position, with or without the application of cocaine, and kept there for the requisite time. This involves no pain and little inconvenience or discomfort. The treatment should be continued for a period extending from a few months in slight cases to about a year or more in extensive cases—i.e., about six short courses at two monthly intervals in serious cases. By this time a serious though favourable case is apparently cured, the slight cases in a very much shorter time.

(*d*) *Methods of Application of Radium.*—In the nose radium may be applied in the form of plates to the outer surface, and in tubes, fastened at the end to a silver wire, to the interior. The tubes can be pushed to any distance into the nasal fossæ, which can if necessary be cocainised previously. In the post-nasal space and on the upper surface of the soft palate the radium is applied by means of similar tubes passed through the nose. In the mouth application is by tube or plates of suitable size; the fauces and soft palate should be cocainised before application. The larynx is treated by external plating.

(*e*) *Action of Radium.*—Broadly speaking, radium has two forms of action. In lethal doses it is a destroyer of living tissue and is used to destroy new growths. But in stimulating doses it has the effect of accelerating the formation of fibroblasts, and so assists the maturing of granulation tissue. When these doses are applied to chronic granulations, such as are found in tuberculous and lupus lesions, they stimulate them to fulfil their function in replacing the disease by scar tissue, and so perform their duties as a natural defence against disease. In chronic lesions caused by the tubercle bacillus, where the spontaneous cure is by fibrosis, radium acts as a powerful ally of Nature. Moreover, its action is selective, and fibrous tissue is laid down only where the presence of the tubercle bacillus has elicited the inevitable tissue reaction, so that just enough and no more scar tissue is laid down to get rid of the disease. This scar tissue is soft and pliable, and no unnecessary rigidity of mobile parts, such as the larynx and soft palate, is produced.

Again, some small patches of lupus are so faint that they cannot be seen by the naked eye. But the radium searches them out, and when the swelling takes place, which marks the reactionary stage of treatment, the presence of minute patches of the disease becomes apparent. The action of radium is therefore more thorough than any treatment dependent upon exact identification by the surgeon. In addition, there is the action of the rays upon the tubercle bacilli themselves.

Many experiments have been made by Mr. A. E. Hayward Pinch regarding the action of radium rays on cultures of the tubercle bacillus, and it has been found that an exposure of at least 100 hours with a full strength unscreened apparatus is necessary to produce a lethal effect. Owing to the tremendous reaction which such a dose would have on the human tissues, radium cannot be used for the purpose of actually killing the tubercle bacillus. It has been noted, however, that cultures of tubercle bacilli which receive a fairly short radiation have their vitality inhibited, and subcultures made from them grow much more slowly than the controls and exhibit numerous involution forms. It is probable, therefore, that the radiation of a lupus patch for a moderate length of time weakens the vitality of the tubercle bacilli, and so enables their ingestion by phagocytes to be more easily accomplished.[1]

(*f*) *Macroscopical Appearances of Healing.*—(1) The reactionary stage. This is at its height in ten days to a fortnight after the application of radium. During this stage any crusts come off of their own accord, leaving a smooth surface. The affected area becomes swollen from œdema and covered with a thin layer of sticky secretion. (2) The healing stage. In another fortnight the same area will be seen to be shrunk below its original diseased condition, and part of it will be covered with fresh mucous membrane over a partial layer of finely striated scar tissue, which, however, is not immediately visible, but can be seen at the end of treatment. This healing process, starting at the edge of the affected area and progressing to its centre, takes place in stages after each course of applications until all the lupus has disappeared. Sometimes the disease is eliminated without any visible formation of scar tissue—a matter of considerable importance in dealing with mobile parts of the throat.

---

[1] Radium Institute Reports.

(*g*) *Restoration of Function.*—This is one of the greatest attributes of radium treatment and is dependent upon its selective and economical action in the laying down of scar tissue. The disease is eliminated and the function of the part restored.

(1) The greatest blessing of this is found in the larynx. Young adults, who have for three and four years been condemned to the life of a recluse owing to their complete aphonia, have within a few weeks been restored to normal and happy human beings and are able to enjoy the usual amenities of life. This has occurred without exception in all the laryngeal cases treated. These cases are in marked contrast to some which are left to themselves, or treated by cautery or scraping, in which thick scar tissue forms, causing incurable aphonia and sometimes necessitating tracheotomy. In contrast to the treatment adopted in tuberculosis of the larynx, where complete rest for the throat is enjoined, the patient suffering from lupus should be encouraged to use the voice as much as possible while under treatment with radium so as to regain whatever suppleness is possible in the scarred muscle tissue and mucous membrane.

(2) In the nose the results are equally satisfactory if less dramatic. The swelling and crusting completely subside, leaving a free airway and often a healthy secreting surface.

(3) The soft palate and fauces, although occasionally scarred, are left in a freely mobile condition, thus assisting the normal return of the voice. In one case where there was more scarring than usual, massage was applied to the part under local cocaine anæsthesia and free mobility restored.

Technical Aspect of Radium Therapy.

1. *Rays.*—For the sake of those who are not conversant with the elementary therapeutics of radium, it may be well to give a very brief account of the rays emitted by its salts. They are of three types: (1) Alpha rays, whose therapeutic power is practically nil, as they are unable to pass through the walls of their containers, and in the case of varnished applicators only a few rays can escape; they are absorbed very quickly, normally at a depth of 0·01 mm. from the surface of the skin.

(2) Beta rays, which are much more penetrating than the above. They are divided into: (*a*) Soft, which cannot pass through 0·2 mm. of aluminium; (*b*) medium, which can pass through 0·2 mm. of aluminium, but not through 0·2 mm. of silver; (*c*) hard, which can pass through 0·2 mm. of silver. The soft beta rays are rapidly absorbed, but the hard beta rays are only reduced to about 6 per cent. of their initial value in their passage through 1 cm. of body tissue.

(3) Gamma rays—these are very penetrating; the radiation which will pass through 2 mm. of lead consists only of gamma rays; so penetrating is their power that it requires a thickness of 14·4 cm. of blood, or 7·6 of muscle tissue to reduce them to 50 per cent.

For the purpose of this paper it may be stated that: A screen of lead, 0·1 mm., allows 23·6 per cent. beta and 99·5 per cent. gamma rays to pass; a screen of silver, 1·0 mm., allows 1·18 per cent. beta and 95·5 per cent. gamma rays to pass; a screen of lead, 2·0 mm., allows 0·37 per cent. beta and 92·8 per cent. gamma rays to pass. To put it shortly, the beta rays are destructive and cause a surface reaction comparable to cauterisation, burns from the first to the fourth degree resulting from an unscreened application, according to the strength and duration of the variation. These changes, however, take place slowly, the summit of the reaction not being reached for about 14 days; the associated gamma rays meanwhile stimulate the growth of fibroblasts and so aid the process of repair, complete healing eventually taking place. By suitable screening this destructive action of the hard beta rays can be modified to the degree required.

2. *Apparatus and its Application.*—The strength of all apparatus described below is expressed in terms of hydrated radium bromide, a salt the radium element content of which is 53·6 per cent. As this salt is deliquescent and unstable, it is always converted into the insoluble sulphate before being fixed in apparatus.

The following methods of treating lupus of the nose and upper air passages were elaborated by Mr. Hayward Pinch in 1911, and have been used at the Radium Institute ever since.

(*a*) When treating the more accessible parts, such as the nares, post-nasal space, fauces, uvula, tongue, and buccal mucous membranes, glass tubes (varying from 1·5 cm. to 4 cm. in length, and from 0·2 cm. to 0·3 cm. in diameter) containing 25 mg. of the salt are used. These are screened with 1 mm. of silver and are covered with rubber, being kept in the desired position by means of either a flexible wire attached, a stout piece of silk threaded through an eyelet at the proximal end, or by using dental wax. As stated above, this screening (silver, 1 mm.) only allows 1·18 per cent. of the beta rays to pass which causes a much modified destructive reaction, the associated gamma rays aiding the process of repair. These tubes are usually retained in position for from two to six hours (not more than two hours at one sitting).

(*b*) Early cases of lupus of the palate are treated with full strength (i.e., 10 mg. to the square cm.) unscreened applicators, covered only with rubber sheeting, for one hour.

(*c*) Chronic cases of lupus of the palate, and also those which have already been radiated, are treated with half strength (i.e., 5 mg. to the square cm.) plates, screened with lead, 0·1 mm., and covered with rubber sheeting; these applicators are retained in position for from one to one and a half hours. Lesions of the gums and buccal mucous membranes are treated in the same way.

(*d*) In treating the larynx, half strength (see above) plates screened with lead, 2 mm., and covered with rubber sheeting are used. These usually contain 40 to 80 mg. of the salt, two or three being applied externally over a thin layer of cotton-wool and fixed in position by strapping and bandages. In this way a purely gamma radiation is obtained, and there is no danger of damaging the skin or intervening tissues. It has been sometimes stated that radium may cause necrosis of the laryngeal cartilages, but no case of this nature has ever been observed at the Radium Institute. From 100 to 200 mg. are used at each sitting of five hours, and this is usually repeated for from three to five days, according to the severity of the lesion.

It will be seen from the above that in a case of average severity a patient will receive about 100 mg. hours (salt) with silver, 1 mm., to each of the more accessible areas, detailed above (*a*), and about 3750 (150 × 25) mg. hours (salt) with lead, 2 mm., to the larynx externally. This treatment is generally repeated at intervals of six weeks to two months, according to progress ascertained by the laryngologist.

In the above description no mention has been made of the "emergent" secondary rays which have such an irritating effect on the tissues; these rays are eliminated by interposing aluminium, 0·2 mm., or several sheets of black paper between the leaden screen and the rubber sheeting.

Appendix of Cases Recently Treated.

Patients suffering from small lupus patches, which have readily healed after radium applications, are not included in this appendix, which contains only the more extensive cases.

The cases have been divided according to the organ principally affected in each case.

1. *Laryngeal cases*—i.e., cases in which the disease affected the larynx as well as other parts of the upper air passages. These are the most extensive and serious cases as far as the upper air passages are concerned. Owing to the patient's aphonia, the condition of the larynx has been the principal consideration in treatment, apart from actual cure.

CASE 1.—Types (A) granulations and (C) tumour formation are exemplified. An unmarried woman aged 24.

History.—Tuberculosis of apex of right lung which had been quiescent for some years. 1918: Developed nasal obstruction due to lupus. Wassermann reaction negative. 1919: Her voice became husky and disappeared altogether. For four years she lived the life of a recluse for fear of infecting others, and also owing to being unable to speak to anyone.

Examination (June, 1923).—General condition good. Tuberculosis of lungs quiescent. Nose: Cartilaginous part bulging as if from large polypi, but in this case caused by extensive crusting within the vestibule. Posterior edges of the vestibule and the anterior ends of the inferior turbinates were covered with large crusts, which also surrounded a perforation of the septum about the size of a threepenny-bit. The nose was almost completely obstructed by the crusts. On removing one of the crusts a swollen and bleeding surface was revealed. Post-nasal space: In the right choana and resting against and attached to the septum was a rounded white tumour about the size of a hazel-nut. Pharynx and fauces: The uvula was rigid and much swollen, with a granular surface. Granulations extended down the posterior left faucial pillar and tonsil bed and both the right pillars and right tonsil bed. The pharynx was heavily scarred from healed lupus. Larynx: Epiglottis scarred, deformed, and apparently healed. Both ventricular bands and vocal cords were thickly covered with granulations, and there was swelling of the interarytenoid region with granular surface. Phonation: The whole larynx was stiff and the cords did not approximate. Voice: Nil. Whisper very feeble and only faintly audible.

Treatment.—Starting from Nov. 5th, 1923, she received short courses of radium treatment at two monthly intervals. These continued for a year.

Result.—After the first application of radium the crusting disappeared from her nose and she was able to breathe through it. Also, within six weeks she found herself able to speak for the first time after a silence of four years. The whole condition has since completely cleared up. Her soft palate was a little stiff, but to this mobility was restored with massage under cocaine anæsthesia by Miss Curling. The voice is still somewhat husky, but is loud and the words clearly audible, and she can speak for any ordinary length of time without increased huskiness of voice or tiredness of the throat.

CASE 2.—Types (A) granulations, (B) vegetations, and (C) tumour formation. The patient, a girl aged 18 years, had for three years suffered from nasal obstruction and complete loss of voice.

Examination.—Nose: Lupus of the vegetating type (B) was protruding from the left nostril. Granulations (Type A) extended through the left nasal fossa as far as the post-nasal space. The posterior half of the right nasal fossa was also covered. Post-nasal space: The posterior ends of both middle and inferior turbinates were affected, also the posterior pharyngeal wall and the superior surface of the soft palate. Pharynx and fauces: The pharynx was much scarred, and the uvula, fauces, and tonsil beds covered with granulations. Larynx: Epiglottis, ventricular bands, and vocal cords were all thickly covered. In the interarytenoid region was a fair-sized lupus tumour (Type C). Voice: Completely absent. Whisper only faintly heard. We had the greatest difficulty in persuading this patient or her mother that she would regain her voice. She had been to the Radium Institute two years previously and been told that the disease was too deep-seated to be attacked by radium.

Treatment.—Courses of radium at two monthly intervals.

Result.—The whole condition has cleared up. There is no nasal obstruction and no scarring except in the posterior pharyngeal wall and epiglottis. The voice returned in four months and is now quite normal, and the patient is able to sing. The palate and fauces are freely mobile and show no scarring.

CASE 3.—Types (A) granulations and (D) ulceration. The patient, a woman aged 35, had for some years suffered from soreness and induration of the lip, and more recently from huskiness of voice, which for the last year had become complete aphonia.

Examination.—Lip: The under surface of the upper lip was covered by old-standing indurated lupus of the ulcerative type. Pharynx: There was a patch of lupus about the size of half-a-crown in the posterior pharyngeal wall. Larynx: The epiglottis was destroyed. Both vocal cords were affected, but the left vocal cord and ventricular band were very thickly covered. Voice: Absent.

Treatment.—Short courses of radium at intervals of two months.

Result.—The voice returned in a few weeks and is now quite normal. The whole condition has made good progress and is nearly healed.

CASE 4.—Types (A) granulations and (D) ulceration. A man, aged 18, had for two years suffered from nasal obstruction and loss of voice, with soreness and stiffness of the back of the tongue.

Examination.—Nose: Lupus granulations over the right inferior turbinate. Post-nasal space: Some scarring of the posterior wall. Palate and fauces: Some ulceration in small scattered patches. Tongue: The whole of the posterior half was covered with massive piled-up granulations. Larynx: The epiglottis very much thickened and swollen. The posterior parts of the vocal cords and the interarytenoid region were affected, and also, to a certain extent, the subglottic space. Voice was almost gone, but the patient could cough and occasionally say some words.

Treatment.—This was carried out according to the usual principles.

Result.—The voice returned and became quite strong though still a little husky. The larynx is healed except for the epiglottis, which is still thickened. The nose and tongue are healed. But the patches in the palate and fauces being of the "ulcerative" type, resisted treatment for some time, but have been arrested and held in check. They have since healed.

2. *Nasal Cases.*—These are cases in which the nasal condition has been predominant, and in which the avoidance of its destruction and disfigurement has been the first consideration in treatment.

CASE 1.—Shows apple-jelly nodules on nose and lip and Type (A) granulations in the nose and pharynx. Patient is a man, aged 18. Had for several years suffered from nasal obstruction, and for one year had noticed spots on his nose and lips, with swelling and crusting of the right nostril.

Examination.—Nose: In the right nasal fossa the granulations extend back to the nasopharynx. In the left nasal fossa there is some slight granulation. Nasopharynx and pharynx: Granulations extend downward behind both posterior pillars of the fauces, which are themselves slightly affected. Larynx unaffected. Neck: Both tonsillar glands are swollen.

Treatment.—The usual line of treatment has been followed.

Result.—The whole condition has made very satisfactory progress. There is now no danger of destruction of the right alar cartilage, and most of the disfigurement already apparent has disappeared. It has since healed.

CASE 2.—Shows apple-jelly nodules on the nose and Type (A) ulceration. The patient, a man aged 21, had for three years suffered from swelling and disfigurement of the nose, with nasal obstruction, and much crust formation in the nostrils. His throat also had been sore and his voice husky for a year.

Examination.—Nose: The whole end of the nose was much swollen and covered with apple-jelly nodules, which also covered the alæ. The vestibule on each side was widely dilated with crusts and granulations extended far into the nose. There was complete nasal obstruction. Post-nasal space: Some scarring and granulations in the superior aspect of the soft palate. Palate and fauces: The whole of the soft palate and fauces and most of the hard palate were covered with a uniform raised red mass of granulations. Larynx: The epiglottis was thickened with granulations and the anterior end of the left vocal cord slightly affected. The voice was husky but not markedly so.

Treatment.—As in the previous cases.

Result.—The case is still under treatment. The nose is now nearly normal and all risk of breaking down and disfiguration has gone. The patient can breathe well through both sides of the nose. The condition of the palate and fauces is rapidly disappearing. The epiglottis is still thickened, but the voice has returned to normal.

CASE 3.—Types (A) granulations and (D) ulceration. The patient is a girl aged 16.

History.—For several years she had suffered from "sore on the nose."

Examination.—These sores were extensive and consisted of red granulating patches on the end of the nose and on the alæ. There was also much crusting in both vestibules, with distension of the nostrils. It was impossible to see any distance into the nose. Mouth: The whole of the soft and hard palates, the fauces, tonsil beds, and the gums of the upper jaw were smothered with lupus of the ulcerative variety. Larynx : The epiglottis and superior surface of the arytenoids were diseased.

Treatment.—Short courses of radium therapy at two monthly intervals.

Result.—Nose : This has much improved. The nose, although not quite normal in appearance, is now free from lupus on the outside. The edges of the alæ, however, are rather irregular. Mouth : The extensive area affected entailed prolonged treatment, but satisfactory progress has been made and the parts involved are now nearly healed. Larynx : Satisfactory progress has been made.

Several other cases have been, and are still, under treatment, but they have not been long enough as yet to justify a report being made.

For the opportunity of treating three of the reported cases the authors are indebted to the courtesy of Mr. Herbert Tilley, Dr. A. M. H. Gray, and Mr. Michael Vlasto.

RECORD OF A BLOOD CRISIS.*

By A. E. SOMERFORD, M.D. MANCH., D.P.H. CAMB.,
FORMERLY ASSISTANT DIRECTOR OF THE CLINICAL LABORATORY, MANCHESTER ROYAL INFIRMARY.

THE significance of a blood crisis lies in the fact that there is a tremendous over-activity of the bone-marrow, by which young immature red cells, some embryonic in type, are thrown into the general circulation in order to counteract the effects of blood loss due to hæmolysis. Though such a crisis is usually of good prognostic significance the efforts of the bone-marrow may be unavailing, as in this case.

E. B., a married woman, aged 42, was admitted to the Royal Infirmary, Manchester, under Dr. E. M. Brockbank's care on June 26th, 1923.

A blood count was taken on the same date with this result : red cells, 1,126,000 per c.mm. ; leucocytes, 3600 per c.mm. ; hæmoglobin, 22 per cent. ; colour-index, 1·0 ; normoblasts, 57 per c.mm. ; megaloblasts, 43 per c.mm.

Differential leucocyte count (per cent.) : Polymorphs, 44 ; lymphocytes, 52·8 ; large mononuclears, 1·6 ; eosinophiles, 1·6 ; mast cells, 0.

The red cells showed a marked degree of anisocytosis, poikilocytosis, and macrocytosis. Punctate basophiles and polychromatophiles were not found, and blood platelets were apparently absent. Though the colour-index was somewhat low, the clinical findings and other features of the blood count were in accordance with the diagnosis of pernicious anæmia which was made.

Further blood counts were made on July 3rd and 10th, and owing to the large numbers of nucleated red cells found on the latter date counts were performed daily until the crisis had subsided.

Date in 1923.	Red cells.	Hæmoglobin.	Leucocytes.	Colour-index.
	per c.mm.	%	per c.mm.	
3/7	1,184,000	24	3600	1·04
10/7	1,408,000	24	6600	0·86
11/7	1,528,000	24	6800	0·80
12/7	1,480,000	24	6600	0·82
13/7	1,416,000	22	6600	0·75
14/7	1,248,000	20	5800	0·80
15/7	1,336,000	20	5000	0·72
16/7	1,352,000	20	4200	0·70
17/7	1,240,000	20	3600	0·83

Date in 1923.	Megaloblasts.	Normoblasts.	Erythroblasts.	Free nuclei.	Punctate basophiles	Platelets.
	per c.mm.					
3/7	100	72	0	0	0	0
10/7	3142	5544	52	0	0	0
11/7	3508	6065	108	897	136	Few
12/7	1768	4382	0	940	66	0
13/7	976	2877	26	871	330	Few
14/7	739	1545	0	690	0	Few
15/7	240	440	0	140	100	0
16/7	33	168	0	151	84	0
17/7	29	72	0	144	0	0

The differential leucocyte counts have been omitted as there was little of interest beyond an increase in eosinophile polynuclears from 0·8 per cent. on July 3rd to 4·4 per cent. on July 12th and 4·8 per cent. on July 14th, after which date the percentage rapidly fell. A relative lymphocytosis of about 60 per cent. was maintained throughout the crisis. Film preparations showed well-marked polychromasia and punctate basophilia. Moreover, there was great variety in the type of nucleated erythrocyte seen. A few cells showed mitotic figures, and in a few apparent extrusion of the nucleus was taking place.

In addition to normoblasts and megaloblasts a more primitive cell, the erythroblast, was observed, a large cell with an intense basophile protoplasm and an oval or round structureless nucleus, stained purple with Leishman's stain. Included in the counts among the megaloblasts were the metrocytes, which cells possess a megaloblastic nucleus with only a narrow fringe of polychromatophilic protoplasm. Cells with oak leaf nuclei were also numerous ; they resemble the normoblasts (with which they were classed in the counts) but the protoplasm is usually polychromatophilic and their nucleus is serrated, resembling an oak leaf. Free nuclei are pyknotic in character, and are small oval or round bodies. In some erythrocytes there were small round bodies which took up the nuclear stain and sometimes formed a complete ring surrounding the nucleus. These are known as Howell-Jolly bodies.

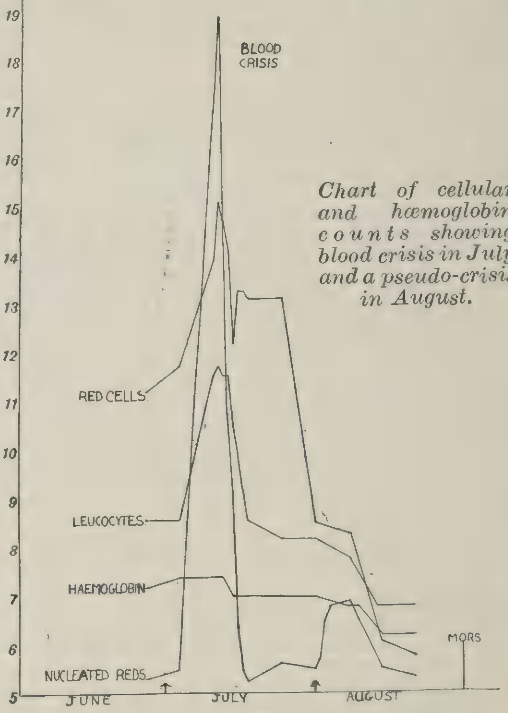

Chart of cellular and hæmoglobin counts showing blood crisis in July and a pseudo-crisis in August.

Blood counts were taken on July 24th and 31st with these results :—

	24/7/23.	31/7/23.
Red cells (per c.mm.)	1,236,000	856,000
Leucocytes (per c.mm.)	3,200	3,200
Hæmoglobin (per cent.)	20	16
Colour-index	0·89	1·05
Normoblasts (per c.mm.)	134	102
Megaloblasts (per c.mm.)	64	64
Erythroblasts . .	0	0
Free nuclei	0	0
Blood platelets . .	0	0
Punctate basophiles	0	0

On August 2nd the patient asserted that she felt extremely well, and as this sense of well-being had been the prelude to the crisis, the possibility of a second crisis was entertained and daily blood counts were made for three days.

The following table shows that there was a definite rise in the number of nucleated red cells though not of sufficient magnitude to warrant a full daily examination :—

	2/8/23. per c.mm.	3/8/23. per c.mm.	4/8/23. per c.mm.
Megaloblasts	96	240	216
Normoblasts	120	216	264
Erythroblasts . .	0	0	0
Free nuclei	48	144	94

---

* Part of a thesis submitted for the degree of M.D. Manch.

From this date the blood value steadily decreased in spite of energetic treatment, and a count taken on August 21st (the day before her discharge home) gave this result: red cells, 576,000 per c.mm.; leucocytes, 1800 per c.mm.; hæmoglobin, 12 per cent.; colour-index, 1·1; normoblasts, 43 per c.mm.; megaloblasts, 14 per c.mm.; other abnormal erythrocytes, 0; platelets, 0.

Differential leucocyte count (per cent.): polymorphs, 28·0; lymphocytes, 67·6; large mononuclears, 2·0; eosinophiles, 2·4; mast cells, 0.

She died on August 31st, 1923, and no post-mortem examination was obtainable.

The chart gives a graphic representation of the occurrence, and it shows also the less-marked increase which might be termed a "pseudo-crisis." The accompanying increase in red cells and leucocytes is also demonstrated, but it will be noted that there was no corresponding increase in hæmoglobin percentage, thus accounting for the low colour-index.

Erythroblasts and megaloblasts are representatives of embryonic regeneration, normoblasts of extra-uterine function, and polychromasia and punctate basophilic cells are evidence of immaturity. Naegeli [1] considered that "free nuclei" were artefacts, and Kölliker that they were normoblasts with an extremely narrow band of protoplasm. They are of interest in so far that, if they represent normoblasts, an increase in their numbers indicates a return of the bone-marrow to its normal function.

I desire to thank Dr. Brockbank for his kind permission to publish the data of this case and for his interest and most helpful criticism.

THE ESTIMATION OF SMALL QUANTITIES OF BISMUTH IN THE URINE.

By CHARLES ALFRED HILL,
SUPERINTENDENT ANALYST, BOOTS PURE DRUG CO.

THE modern therapeutic use of bismuth and its compounds has rendered the estimation of small quantities of bismuth, especially in urine, a subject of interest, and among the fundamental reactions which are available, the conversion of bismuth into an alkaloidal bismuth iodide, which is also the reaction used in Dragendorff's test for alkaloids, appears to be the most promising. The reagent for the detection of bismuth suggested by Léger [2] consisted of 1 g. of cinchonine and 2 g. of potassium iodide dissolved in 100 c.cm. of water. Excess of this reagent added to a solution containing free nitric acid, but not free hydrochloric or sulphuric acid, gave a reddish bismuth cinchonine iodide precipitate in the case of appreciable quantities of bismuth, but giving a red colour with traces. An attempt to make this method quantitative resulted in failure, and unless the conditions were very carefully adjusted one could not be sure of getting the red bismuth cinchonine iodide rather than the greenish-yellow of bismuth iodide, slight differences in dilution, excess of reagents, &c., making a very marked difference in colour. Also, the cinchonine itself lends a fluorescence which interferes. It was found that by dividing the reagent into two parts, adding the cinchonine in excess, followed by the addition of potassium iodide in small amounts, the concentration being kept as high as possible, the reaction resulted in the formation of a fairly constant and maximum red colour. Caille and Viel [3] recommend as a reagent for the detection of bismuth in biological fluids a solution consisting of 1 g. antipyrin and 2 g. potassium iodide in 30 c.cm. of water. Their method was to destroy the organic matter by ignition and subsequently to dissolve the ash in nitric acid and evaporate. The ash was then dissolved in hydrochloric acid and the reagent added. This method failed to give consistent results, not only because the yellowish-green colour masked the red compound, but, as Léger had pointed out, the hydrochloric acid should be eliminated and not introduced. Also, the addition of hydrochloric acid to the residue after treatment with nitric acid would tend to produce chlorine, which would liberate iodine and spoil the results. The possibility of the production of nitrous acid seems to have been entirely ignored, though unless its presence is guarded against, the results would be quite useless owing to the continued formation of iodine. A further difficulty was encountered in the destruction of the organic matter in substances such as urine. It was found that unless the ignition was complete, the bismuth would be retained by the undestroyed organic matter, while if the temperature on ignition was too high some of the bismuth was converted into an insoluble form which could not be taken up by nitric acid and, after considerable experiments, the following method was devised, more particularly for the estimation of urine.

To Destroy the Organic Matter.

As the amount of bismuth is usually unknown, and as it is desirable to carry out the final colorimetric matching in a solution containing about 0·05 mg., in 50 c.cm. three separate quantities of 5, 20, 50 c.cm. each of the urine should be measured into separate silica beakers of 100 c.cm. capacity and evaporated on an asbestos board over a bunsen flame to about 5 c.cm.; the beakers are removed and 5 c.cm. of S.G. 1·4 nitric acid added, the basins replaced on the asbestos and evaporated to dryness and heated at the lowest possible temperature, so that the organic matter is oxidised but not charred; it is important to stop the ignition when all the nitric acid is driven off and then to remove, cool, and moisten with more nitric acid; again, the evaporation and heating are repeated with previously mentioned precautions and if necessary the procedure repeated with further small quantities of nitric acid until a white residue remains. After cooling, two drops of nitric acid and 25 c.cm. of distilled water are added and the solution boiled for a few minutes and transferred to a Nessler cylinder; if the lowest temperature for the destruction of the organic matter has been maintained, it will be unnecessary to filter the solution which should be perfectly clear and colourless. After rinsing out the beaker with further quantities of boiling water, the volume is made up to 50 c.cm. and cooled.

To Determine the Bismuth.

To the solution in the Nessler cylinder add 0·3 g. of urea, dissolve, and mix thoroughly, then add 0·5 g. phenazone, agitate to dissolve, and while still shaking add potassium iodide in very small crystals (average weight 0·05 g.) one at a time until a red colour appears; it will be readily seen when the maximum colour develops, then add one crystal in excess. The colour is quite easily imitated with a standard solution of bismuth made by dissolving 0·62 g. of bismuth carbonate B.P. in 10 c.cm. nitric acid (S.G. 1·4) adding water to 1000 c.cm., and further diluting 10 c.cm. of this to 1 litre. The best results in the control experiment are obtained by taking 10 c.cm. of this solution (equivalent to 0·05 mg. of bismuth, Bi) and 1 drop HNO_3 (S.G. 1·4), adjusting to 50 c.cm. in the Nessler cylinder and adding the reagents as the method specifies, and the comparison is made with the solution giving the most suitable depth of colour.

Test results to show the accuracy of the method were made by adding known amounts of bismuth to varying quantities from different samples of urine and treating as described. In every experiment the colour obtained was equably comparable with the blank containing the same amount of bismuth. Four individually different samples of urine into which no bismuth was introduced failed to produce any colour when similarly treated.

I wish to express my thanks to Messrs. Boots Pure Drug Co., in whose laboratory the work was carried out, and to Mr. H. Droop Richmond, F.I.C., for his interest and advice, and to Mr. J. A. Egglestone, B.Sc., for assistance in the experimental work.

MARGARINE IN MENTAL HOSPITALS.—The West Riding Mental Hospitals Board have rejected the recommendation of the Board of Control that 25 per cent. of the patients' allowance of margarine should be substituted by butter, on the ground that the diet already contains an adequate amount of fat. It was stated that butter would cost £2442 a year more than margarine.

NOTE ON A

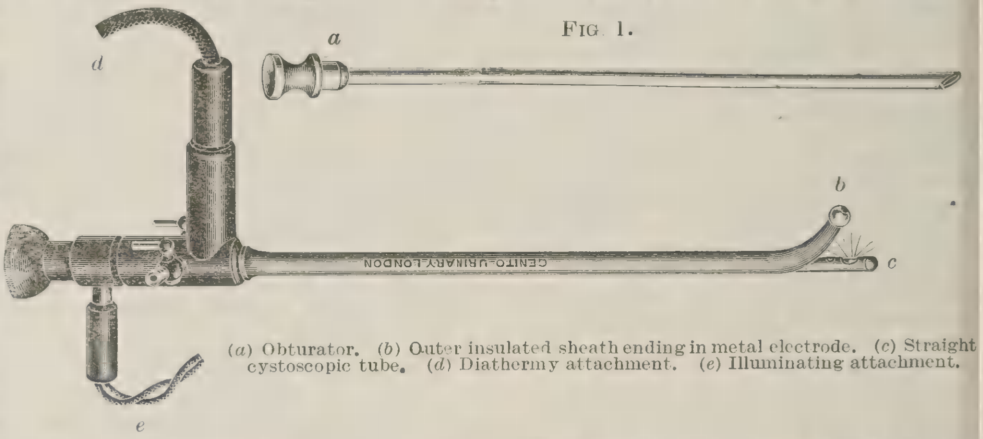
CYSTOSCOPE OF NEW TYPE

DESIGNED FOR THE APPLICATION OF DIATHERMY TO BLADDER TUMOURS.

BY FRANK KIDD, M.CH. CAMB., F.R.C.S. ENG.,
FORMERLY SURGEON TO THE LONDON HOSPITAL.

NOTHING can give more satisfaction to the surgeon than the ability to destroy a papilloma of the bladder without opening the bladder by means of diathermy applied with the catheterising cystoscope, a method we owe to the genius of Edwin Beer. By this means I have destroyed 48 cases of simple and malignant papilloma out of 72 cases treated. Nevertheless, it has long seemed to me that there was room for improvement in the technique. Through the ordinary catheterising cystoscope only a small electrode can be employed, with the result that it takes on an average at least three sittings to destroy a papilloma of ordinary dimensions. For a long time I have been thinking how I might devise a technique whereby a large electrode could be applied cystoscopically, so that I could hope to attain the destruction of a tumour at a single sitting, as is quite feasible if the bladder is opened by an incision and an electrode of large dimensions employed.

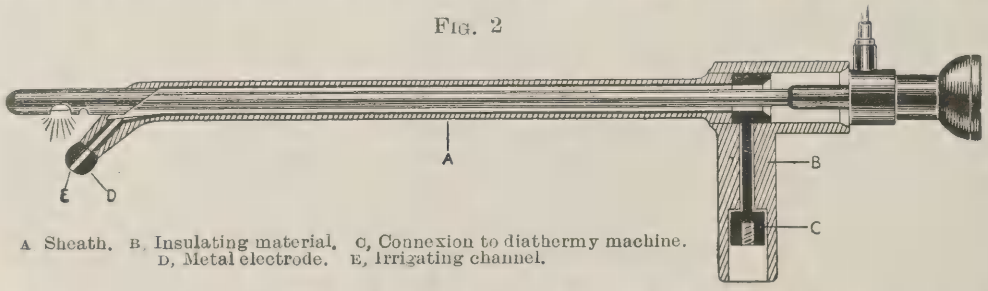
FIG 1.



(*a*) Obturator. (*b*) Outer insulated sheath ending in metal electrode. (*c*) Straight cystoscopic tube. (*d*) Diathermy attachment. (*e*) Illuminating attachment.

At length this idea has been made a practical reality by the invention of "bakelite," a material which is capable of sterilisation in boiling water, and which is a perfect insulating material. When this substance was brought to my notice by Mr. Schranz, of the Genito-Urinary Manufacturing Company, London, I told him of my idea and suggested a means whereby the problem could be solved. The result is the cystoscope which I am now bringing forward. I believe that this cystoscope is a new departure, and that it is likely to give quick results which have hitherto been quite impossible of attainment with the ordinary catheterising cystoscope. The idea is to use the cystoscope itself as the diathermy electrode, a large electrode as compared with the tiny electrode so far used through the catheterising cystoscope of the Nitze-Albarran type.

FIG. 2



A Sheath. B, Insulating material. C, Connexion to diathermy machine. D, Metal electrode. E, Irrigating channel.

The cystoscope consists of an inner tube of metal which is connected at its proximal end to one pole of a powerful diathermy machine, and which terminates at the distal end in a large metal ball perforated by a hole to permit of the circulation of irrigating fluid. This metal tube or electrode is insulated with "bakelite" except at its terminations, and is passed into the bladder armed with a metal obturator, the whole instrument being of a size No. 24 Charrière. The instrument is passed into the bladder, the obturator withdrawn, and the bladder washed clear and distended for inspection. Through the lumen of the tube is then inserted a straight lens-holding tube or cystoscope. This is insulated at its distal end by a sheath of "bakelite." The lenses are arranged in such a manner that a large field of bladder can be seen, and when the cystoscopic tube is rotated to a suitable angle, the rounded metal end of the cystoscope can be seen as it projects at an angle to the main body of the instrument. Nothing then remains but to apply this large electrode under the sight of the eye to the tumour in the bladder and to destroy it completely at one sitting by means of diathermy. The largest and most powerful diathermy machine can be used with this electrode and the tumour be destroyed just as if it were exposed at an open operation. As the field becomes clouded with detritus, the bladder can be washed clear through the cystoscope without any need for the withdrawal of the sheath from the bladder. It is advisable to employ a cold lotion of oxycyanide of mercury 1 part in 4000, and to empty and refill the bladder frequently as one proceeds, otherwise the lotion may rapidly become heated to an excessive degree by the heat generated at the electrode.

I believe that this instrument presents an advance in the treatment of papilloma of the bladder. Some surgeons appear to have lost patience with diathermy and are inclined to open the bladder for papilloma. Open operation has a definite mortality, and it is always liable to risk of recurrence in the scar. Diathermy applied through the cystoscope has no mortality and leads to no risk of implanting fresh tumours elsewhere in the bladder.

As an example of what it is possible to effect by means of this instrument I can quote the following case:—

A woman was sent to me in April, 1925, by Dr. H. Fraser of Harpenden. She had an ulcerating carcinoma some tw inches in diameter lying between the right ureter and th internal meatus extending on to the right lateral wall She was suffering from severe painful cystitis and hæmaturia Under anæsthesia I burnt over the whole floor of the ulce with the new diathermy cystoscope, and then implante 12 radium emanation seeds through another cystoscope int the charred base. For some months there followe increasing pain accompanied by the passage of larg sloughs through the urethra. I examined her in November 1925. She had no pain, no hæmaturia, no increase frequency, and the urine was as clear as crystal. On inspecting the bladder with the cystoscope I could see that the malignant ulcer had completely disappeared.

This was a case that was quite inoperable by any of the older methods and might have been condemned to an early and painful death. The treatment applied has caused the ulcer to disappear and the bladder to take on the appearances and sensations of complete health.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF OPHTHALMOLOGY.

A CLINICAL meeting of this Section took place on Dec. 11th at St. Thomas's Hospital under the presidency of Sir ARNOLD LAWSON.

Inflammatory Deposit in Cloquet's Canal.

Mr. MALCOLM HEPBURN showed a woman, aged 33, who had a metastatic inflammatory deposit in Cloquet's canal in both eyes. A mass could be seen to be filling up the central part of the vitreous, and around this the fundus, apparently normal, was visible. He had watched the eyes for two years, but had seen no sign of inflammation. Had the appearance been due to hæmorrhage he thought it would not have been stationary, and it would not have lasted so long. He feared that there would be some shrinking of the vitreous in the future.

Central Retinitis.—Band-shaped Opacity of Cornea.

Mr. A. C. HUDSON exhibited two cases of central retinitis, showing the condition in two stages. The more advanced one he brought forward three years ago, when it was at the stage that the more recent one illustrated now. There was apparently a calcification of the retina in the macular region and some disturbance of retinal pigment. In addition, there were a number of minute bright dots scattered over the foveal region. Usually the condition was unilateral, but he had had at least one case in which a very similar state was present in both eyes. In many of these cases the vision was certainly not very seriously impaired. In several, however, the patients complained not only of defective vision, but of seeing through a violet haze or mist. One of the two patients shown to-day said he seemed to look through a green veil; both of them had a central scotoma for red. Wassermann in both was continuously negative. He suspected some form of toxic absorption, perhaps from the air-cells (ethmoid, sphenoid, or frontal sinus). After weeks, even months, of treatment the sight remained much the same. Mr. Hudson also showed a patient with a primary band-shaped opacity of the cornea, whom he exhibited first two years ago. Scraping in such case produced a good result, and there was but little reaction following the procedure. Before the operation vision was 6/18 (partly), and it was now 6/9.

Ichthyosis of the Skin with Ectropion.

This patient, also demonstrated by Mr. Hudson, had congenital ichthyosis and very severe ectropion in each eye. The right eye had been quite destroyed. In the left eye was an extensive chronic keratitis in a very irritable stage, and apparently threatening to extend. Under the circumstances it seemed unlikely that much good would follow tarsorrhaphy, as there was so much tension on the skin, and union did not seem probable. But Thiersch grafting seemed advisable, if a suitable graft could be found. He decided on taking a graft from the outer surface of the patient's arm. Instead of being supple, however, this had the consistency of parchment. Still, as a bleeding surface was left behind, it was clear that living cells had been cut through. The graft took well, and the eye was now satisfactorily closed during sleep.

"Black Cataract" and other Cases.

Mr. Hudson next showed two cases of black cataract. The woman patient was at once seen to have very widely dilated pupils, and was obviously nearly blind. With the light from the window a grey pearly reflex was seen, apparently coming from behind the lens. She said she had a severe blow on that eye, and that she lost the sight of it two years afterwards. The pupil was now inactive and the projection very bad. From the better eye he extracted a cataract. There was an enormous lens, almost the colour of a prune. Vision was now 6/18 without glasses. The man with the black cataract had a healthy fundus, and with a sphere the vision was 6/9. Usually some fundus disease was present in these cases.

Mr. Hudson showed a man with buphthalmos and neurofibromatosis of fifth nerve. Mr. Treacher Collins had suggested that the buphthalmos depended on a defective development of the angle of the anterior chamber, and not upon any peculiarity of the nerves of the eye. This man's eye was so injected and irritable that Mr. Hudson thought it ought to be removed.

Mr. Hudson demonstrated a case, shown by Mr. K. G. W. SAUNDERS, of double leukoma adherens which appeared to be unique. Curiously, the tension of the eye was not raised, for with the iris applied to the back of the cornea over practically its whole extent some increase of tension was to be expected.

Ectodermal Cyst of Iris.

Mr. P. G. DOYNE showed a woman, aged 46, who had a cyst of the iris. She attended hospital and asked for an operation to be done. Vision was full in both eyes. On dilating the eye, a dark cystic condition became apparent in the lower and outer third of the iris. It was somewhat translucent, and the eye transilluminated readily from the limbus. The tension of the eye was normal.

SECTION OF ANÆSTHETICS.

A MEETING of this Section was held on Dec. 4th, Dr. F. W. SHIPWAY, the President, in the chair, when Prof. M. S. PEMBREY, F.R.S., read a paper on

Apnœa, Dyspnœa, and Cyanosis in Relation to Anæsthesia,

supplemented by clinical remarks from the President. Prof. Pembrey described apnœa as the absence of respiratory movements. In the fœtus there is prolonged apnœa, but the fœtus born before full term is capable of breathing. This appears an exception to the rule that muscular work needs progressive training. It is not really so, for Ahlfeld has shown that muscular contractions of a rhythmic nature occur within the uterus and appear to be respiratory and due to stimulation of the medulla from gaseous interchange in the blood. A fœtal sheep was removed from the uterus without damage to the placental circulation, and stimulation of the skin did not cause respiratory movement; but the animal began to breathe directly the umbilical cord was tied. The effective stimuli result from changes in blood composition, and cutaneous stimuli are only an accessory influence on the respiratory centre whose excitability is low in the fœtus and the infant, as they can stand deprivation of oxygen and accumulation of carbon dioxide better than the adult. The young mammal retains characteristics of its cold-blooded ancestors. Apnœa is not due to oxygen excess, as has been demonstrated by observations on hibernating animals. In infants Cheyne-Stokes breathing is common and physiological. In the old, also, this type of breathing may have no relation to disease. Air containing more than 2 per cent. of CO_2 abolishes apnœa by maintaining the tension of that gas at its stimulating value. Prof. Pembrey described the postural apnœa of diving birds, reflex inhibition of respiration in drowning, and the apnœa of forced breathing. Dyspnœa, he said, is the counterpart of apnœa. The former is evidence of vigorous respiratory stimulation, the latter denotes its absence.

The PRESIDENT deplored the instruction to patients to "breathe deeply." Rapid induction of anæsthesia cannot be obtained without a sense of discomfort. Acapnia may occur during prolonged gas-oxygen anæsthesia, and can be abolished by rebreathing. A condition may arise clinically in which, although the patient is fully oxygenated, he suffers from anoxæmia, oxygen having facilitated escape of CO_2 to too great an extent. Apnœa is seldom seen during "open" ether, the administration being really a "semi-open" one. The President referred to various muscular movements and forms of rigidity due not to insufficient anæsthesia, but in reality to anoxæmia, and he related a case showing the enormous importance of the presence of mucus in the lower air passages.

The papers were discussed by Dr. S. R. WILSON, Mr. G. R. PHILLIPS, Mr. LANGTON HEWER, and others.

MEDICAL SOCIETY OF LONDON.

TREATMENT OF GENITO-URINARY TUBERCULOSIS.

AT a meeting of this Society on Dec. 14th, with Sir HOLBURT WARING, the President, in the chair, a discussion took place on the treatment of genito-urinary tuberculosis in the male.

Renal and Vesical Disease.

Mr. CYRIL A. R. NITCH, in opening, spoke first on renal tuberculosis. Bacilli, he said, reached the kidney from some other focus in the body, either a quiescent and obscure lesion such as a tuberculous mediastinal gland, or an active and obvious source such as pulmonary, articular, or osseous tuberculosis. These two sources of infection, generally speaking, gave rise to two distinct clinical types of renal tuberculosis, respectively surgical and medical. As surgical renal tuberculosis was primarily unilateral, and as spontaneous cure was practically unknown, the treatment was by early nephrectomy. Before an operation was performed the function and condition of the opposite kidney must be carefully investigated. This having been done, in an ordinary case of unilateral disease the kidney should be removed with its capsule and any adherent perinephric fat by the lumbar route. Nephrectomy was contra-indicated when the function of the opposite kidney was defective (unless the deficiency was solely due to accompanying toxic nephritis) in advanced bilateral tuberculosis, and when the disease was secondary to pulmonary or other gross tuberculous lesions. With regard to treatment of the ureter, Mr. Nitch's own practice was to remove the entire ureter whenever it was obviously diseased, with a view to preventing further infection of the bladder, and also to accelerating its recovery. In 22 cases there had not been any operative mortality, and he considered that the results justified the operation, which he described in detail with the aid of drawings. Though ureterectomy might not be considered necessary in every case, it was definitely indicated as a primary operation when the ureter was much enlarged and dilated. He spoke of 60 per cent. of cures.

Vesical tuberculosis was twice as frequent in men as in women, and was always secondary to renal or genital tuberculosis, or, rarely, to tuberculous salpingitis by direct extension from an adherent tube. The disease extended in a downward direction to the prostate, the urethra, the seminal vesicle, and the epididymis. The immediate treatment, therefore, consisted in removing either the affected kidney or the affected portion of the genital tract. When the diesase was complicated by both renal and genital tuberculosis, the kidney must be removed first and the lesion of the genital tract at a later date. The results of such drastic treatment were often so remarkably good that extension of the disease to the genital tract after nephrectomy should not deter the surgeon from a second radical operation. In many cases the bladder eventually recovered without further treatment, but in a considerable proportion pollakiuria and pyuria persisted and required both general and local treatment. General treatment consisted of rest in healthy surroundings, bladder sedatives, cod-liver oil when tolerated, and tuberculin. In his experience the best form of local treatment was surgical diathermy at intervals of a fortnight or three weeks, but the operator should aim at singeing rather than coagulating the surface. He added a few words with regard to genital tuberculosis, leaving this subject chiefly to the following speaker. In tuberculous epididymitis he found the operation of epididymo-vaso-vesiculectomy devised by Loughnane to give excellent results, and removal of a portion or the whole of the prostate was only necessary in advanced cases.

Genital Disease.

Mr. KENNETH M. WALKER said that it was impossible to discuss the treatment of genital tuberculosis without referring to its pathology. Pathology taught that genito-urinary tuberculosis was never primary, it was always the result of a focus elsewhere in the body, and most commonly in the lungs, the bones, or lymphatic glands. The post-mortem room demonstrated the frequent association of tuberculosis of the genitalia with similar lesions of the urinary system, but he was inclined to think that it was only in about 45 per cent. of cases that the urinary system was attacked in conjunction with the genital. As a rule the disease appeared first in the urinary system and then spread to the genitalia. No figures were available as to how often the disease took the reverse course, appearing first in the genitalia and afterwards involving the urinary system. Such figures would be of extreme value, for by their means one would be able to gauge the success of various forms of treatment that might be employed in cases which appeared to be pure genital tuberculosis, since it was the risk of spread to the urinary system that constituted the chief danger. His own feeling was that when a genital tuberculosis spread to the urinary system it was the bladder that became infected through the prostate and seminal vesicles, and that the appearance of a renal lesion almost always meant that the infection started primarily in the kidney. With regard to the direction taken by the disease in the genitalia, he felt strongly that the path was the same as that taken by the gonococcus or any other organism that was known to attack the urethra primarily and the epididymis by secondary spread down the cord. Blood-borne infections of the testicle almost invariably affected the testis first, but in tuberculosis, as in gonorrhœa, the lower pole of the epididymis was the site at which a lesion first appeared. Personally he regarded the prostate and vesicles as playing a very sinister part in the spread of tuberculosis from the urinary to the genital system. If it were not for these structures a tuberculous testicle would be as rare as a tuberculous ovary. He gave figures which furnished evidence in favour of the descending route of infection; the spread of the disease was, he believed, from the prostate or vesicles to the epididymis rather than in the reverse direction.

A rational treatment based on this pathology must recognise two important points. The first was that reliance could not be placed entirely on surgery, but that general constitutional treatment was as important as local extirpation by the knife Indeed, in many cases surgery was entirely supplementary to treatment by means of open air, cod-liver oil, tuberculin, "artificial sunlight," &c. I the case was one of pure genital tuberculosis the tendency was towards encapsulation and cure Genital tuberculosis was on the whole a benign disease It was genito-urinary tuberculosis rather than pure genital disease that did badly. In the presence of urinary disease constitutional treatment alone failed utterly. The spontaneous healing of a focus in the kidney was a rare event, and the only hope of salvation was in surgery. The first step, therefore, in the treatment of a patient suffering from genital tuberculosis was to make sure that no disease existed in the urinary system. Should a focus be found in the urinary tract surgical measures must be adopted, and once the urinary condition had been satisfactorily dealt with an improvement would take place in the genital disease and constitutional measures would begin to have effect. The second lesson to be drawn from the pathology was that if the theory were accepted that the disease started in the prostate and vesicles and spread to the epididymis, even such a wholesale measure as castration must fail to eradicate the disease. Should it be the aim of the surgeon to remove entirely the infected tissue, he could only do so by means of a complete extirpation of the genital tract. Whatever might be thought of Mr. Hampton Young's radical operation, it was the only logical one from the point of view of complete removal of infected tissues. To remove the testicle and vas as far as the internal ring and to leave behind an infected prostate and vesicle was an incomplete operation; it might be justifiable provided it was recognised that all that had been done had been to remove grossly infected tissues in order to assist the body in overcoming the infection that still remained. The speaker was in favour, whenever possible, of performing an epididymectomy rather than an orchidectomy. It was surprising how little the patient appeared affected by epididymectomy, and should the opposite epididymis become infected later the patient gladly submitted to what he regarded as a very trifling operation. But epididymectomy or even orchidectomy generally left behind central lesions in the prostate and vesicles, and the only logical operation if it was the intention of the surgeon to extirpate the disease by means of the knife was the complete excision of the genital tract. This was so severe a measure that it should be reserved for exceptional cases, in which other measures had failed, and the patient was obviously going downhill. In the majority of cases the only surgical measures required were epididymectomy, orchidectomy, the opening of abscesses, and the scraping of sinuses.

The Pathological View.

Dr. S. R. **Gloyne** pointed out that his experience of renal tuberculosis was chiefly confined to the medical form frequently associated with pulmonary tuberculosis. This form generally showed small tubercles n the cortex and beneath the capsule, and was almost certainly a blood infection of an embolic nature. He also dealt with a number of points with regard to laboratory examination of urine, &c. He suggested that there was probably more than one species of smegma bacillus and that various workers appeared to differ considerably in their technique of differentiatng this bacillus from *B. tuberculosis* by decolorisation with alcohol. The only safe way of differentiation appeared to be by making careful controls with different amounts of decolorisation, by comparing with known cultures of *B. tuberculosis* and by taking care in obtaining clean specimens by catheter. There seemed to be definite evidence that true tubercle bacilli could be excreted by the kidneys without lesions in renal tissue. Cases were also occasionally recorded in which there were tubercle bacilli present n the urine without casts or pus cells, but it was generally possible to find pus cells if adequate centriugation was employed. In doubtful cases it was mportant to collect and sediment the whole of the urine passed during 24 hours. The animal inoculation est was not entirely satisfactory. Cases of renal uberculosis were sometimes found in which guinea-pig inoculation failed, and there was always the difficulty of having to wait two or three weeks or ven longer for a result. Secondary infections in enal tuberculosis were probably commoner than was generally supposed. With regard to treatment, it was difficult to estimate the value of tuberculin in all hronic forms of tuberculosis, and renal tuberculosis was a good example of this difficulty. To give very small doses was the only safe rule. Sanocrysin and other chemotherapeutic remedies derived from the heavy metals were liable to produce toxic nephritis and were not likely to offer much scope in renal tuberculosis. There occasionally appeared to be some evidence of spontaneous healing of small tuberculous lesions in the kidney and from time to time cases of cure were reported, but the speaker considered that in his experience the 2 per cent. of clinical healing given by Keyes in his recent text-book was excessive. In conclusion, not only was early diagnosis of renal tuberculosis essential, but also a careful search for other foci of disease. The complement-fixation test might be relied upon when it was positive, but negative reaction was of no value.

Discussion.

The **President** mentioned a case which had come within his experience of apparently spontaneous healing of renal tuberculosis, verified by surgical discovery of a calcareous nodule in the kidney.

Mr. **Jocelyn Swan** agreed with Mr. Nitch that a patient with a bad tuberculous kidney, even with tuberculous infiltration in the vesicle and prostate, was a perfectly good surgical risk, and could be cured. He would raise Mr. Nitch's estimate of 60 per cent. of cures to 75 per cent. His own operation, which he described in detail, varied a little from that described by Mr. Nitch, but he agreed that the whole length of the ureter should be removed at the same time as the kidney was removed, because otherwise the operation would be incomplete, leaving virtually a test-tube of tuberculous material in the ureter. In the case of the bladder the post-operative treatment was just as important as the operative. Generally speaking, vesicular tuberculosis was secondary to renal or genital tuberculosis, but he had seen one case which was undoubtedly primary tuberculosis of the bladder. The less one did in the way of local treatment of the bladder the better; once the primary focus in the kidney was removed, it was astonishing how the bladder condition cleared up.

Dr. **Nathan Raw** said that in cases of primary pulmonary tuberculosis it was remarkably rare for the kidney to be affected. On the other hand, in cases of primary genito-urinary tuberculosis the number of subsequent infections of the lung was larger. On the question of tuberculin he had come to the conclusion that although this was an extremely valuable remedy it ought not to be prepared from toxic cultures. He would strongly urge that cultures which had been attenuated should be used.

Mr. J. E. H. **Roberts** mentioned the rarity of genital tuberculosis among patients who were the subjects of the pulmonary condition. In operating he had, as a rule, removed the testis, epididymis, and cord as far as the internal ring. In most of the cases there was tuberculosis also in at least the vesicle on the same side, and also definite nodules in the prostate. After the operation he treated by means of therapeutic X rays applied to the vesicle and prostate and to the course of the vas between the internal ring and the vesicle. In every case the rapid disappearance of the lesion after X ray treatment had been surprising. A necessary preliminary, of course, was to remove surgically any large masses of tuberculous disease present.

Dr. **Rolf Creasy** said that every speaker had rightfully emphasised the necessity for beginning with very small doses of tuberculin, but it was not until the big doses were gradually worked up to that the beneficial effects would be felt.

Sir **Henry Gauvain** remarked on the rarity of the condition amongst children. Out of some 4000 cases which had passed through his hands at Alton, he could recall only two of renal tuberculosis.

Mr. **Nitch**, in replying, said that in assessing his figure of 60 per cent. cures after ureterectomy he had included only those cases in which 24 hours' specimens of the urine had been obtained and showed no pus, and, of course, no tubercle bacilli.

Reviews and Notices of Books.

Manipulative Surgery.

Principles and Practice. By A. G. Timbrell Fisher, *M.C.*, F.R.C.S. Eng., late Hunterian Professor, Royal College of Surgeons of England; Surgeon, Seamen's (Dreadnought) Hospital, Greenwich. London: H. K. Lewis and Co., Ltd. 1925. Pp. 168. 7*s.* 6*d.*

The astonishing advances which have taken place during the last 40 years in the more scientific aspects of surgery have had one unfortunate result—they have tended to obscure the importance of those simpler methods of manipulation upon which our fathers had so largely to depend. They have, indeed, aroused a positive antagonism between those who are trained in the surgeon's art and those who depend for their results on the skill of their hands and the quickness of their wits. In the present volume an attempt has been made to explain the means by which the bonesetter has sometimes succeeded in confounding the man of knowledge, and to reduce manipulative surgery to something approaching a scientific basis. Commencing with a short discussion of the pathology and diagnosis of the minor disabilities of the joints, Mr. Fisher proceeds at once to a detailed description of their manipulative treatment. Taking first the knee-joint, upon which he himself has done a great deal of original work, he discusses various joints and their disabilities in great detail, illustrating his remarks by descriptions of typical cases and with photographs which make his meaning abundantly clear. The book should be of value to all who have to deal with injuries of the joints, and it may help to remove from surgery a not entirely unmerited reproach.

Gynæcological and Obstetrical Monographs.

Appendix (1925). London and New York: D. Appleton and Company. 1925. Pp. 224. 12*s.* 6*d.*

These monographs were published in America in 1922. Each of the 15 volumes was written by a recognised authority on the subject and the whole series then constituted an excellent survey of this important branch of medicine. During the past two or three years many important contributions to the literature have been made, and the authors of the various articles have at the request of the publishers furnished the material which has brought the subject-matter of each volume up to date. This material is now incorporated in one volume as an appendix and forms an exhaustive review of recent work both in America and on this side of the Atlantic. An extensive bibliography with numbered references is appended and should prove valuable to the student and the research worker. We can recommend this book not only to those who possess the original set of monographs but also to those who are interested in recent advances in obstetrics and gynæcology.

Physics.

The Spectroscopy of X Rays. By Manne Siegbahn, Professor in the University of Upsala. Translated with the Author's additions by George A. Lindsay, Assistant Professor of Physics in the University of Michigan. London: Humphrey Milford, Oxford University Press. 1925. Pp. 287. 20*s.*

No book could better exemplify the readiness of the scientific world to make use of a discovery than this one by Prof. Siegbahn. In 1912 Laue discovered the way to measure the wave-lengths of X rays. In spite of the war years, investigation was pursued on the subject, and to-day the spectroscopy of X rays is of such importance as to warrant a text-book to itself. Here we have an excellent one, of which the scope may be inferred from the titles of the chapters. Following a summary of our knowledge of X rays up to the time of Laue's discovery, there are chapters on the Interference of X Rays, Technique of X Ray Spectroscopy, Emission and Absorption Spectra, Theories of X Ray Spectra, the Continuous X Ray Spectrum, and a chapter on the Inner Energy Levels of the Atoms. There is, of course, abundance of material here far beyond the ordinary needs of the medical radiologist, but for purposes of reference he will find the book worthy of a place beside Rutherford's "Radioactivity" on his shelf. The section dealing with spectroscopic apparatus is, however, of special interest, for medical men have often wished to avail themselves of some type of instrument which would give them ocular demonstration of the radiations they are using, and, in this book, they will find the various types well described and their particular merits differentiated.

The translation has been done by Prof. G. A. Lindsay and, on the whole, deserves warm praise. The book is a very valuable one; it is written by one who has contributed largely to the elucidation of the subject and meets a want which has been felt for some years.

Photo-Electricity, the Liberation of Electrons by Light. With chapters on Fluorescence and Phosphorescence, Photo-Chemical Actions, and Photography. Second edition. By H. Stanley Allen, M.A., D.Sc., F.Inst.P., F.R.S.E., Professor of Natural Philosophy in the University of St. Andrews; sometime Senior Lecturer in Physics at University of London, King's College. London: Longmans, Green and Co. 1925. Pp. 320. 18*s.*

Prof. Allen's Photo-Electricity now appears in a somewhat enlarged form, not too cumbrous, however, for easy reading. The subject-matter is not restricted to photo-electricity—i.e., the liberation of electricity by light—but includes chapters on Fluorescence, Phosphorescence, Photo-Chemical Actions, and Physiological Effects. Perhaps the last named is the section, brief as it is, which will appeal particularly to medical readers. Among the various physiological reactions discussed in this connexion is that of vision. The author says: "It is sufficient to suppose that photo-electric action takes place in the chemical substance (or substances) contained in the rods or cones, such separation of electrons resulting in electrification of the nerve-cells which sets up the nervous impulse to the sensorium. The changes in the retina on this view are identical with those in a phosphorescent substance or in the formation of a latent image on the photographic plate. The after-images seen in the dark after viewing a brightly illuminated object are analogous to phosphorescence, the excitation of the retina being due to the separation of electrons, the after-image to their return." While there is little escape from the probability of photo-electric action of the retina under appropriate stimulus, its mere recognition can hardly, we feel, be put forward as a theory of vision. The book is furnished with a bibliography of scientific papers, published from 1913–24, relating to photo-electricity, which should prove of considerable use to readers.

La Physique des Rayons X, à l'Usage des Médecins. Par Loisel, Préparateur de Physique à la Faculté de Médecine; et Lomon, Radiologiste des Hôpitaux, Chef des Travaux pratiques de Physique à la Faculté de Médecine. Préface du P. André Broca. Paris: Masson et Cie. 1925. Pp. 150. 10*s.*

This book on the physics of X rays for the use of doctors will prove useful to them, though they may think that the facts of gaseous ionisation are more easily grasped unassociated with mathematical treatment. The book is divided into three parts: the first is devoted to a description of the means of production of X rays; the second is upon the nature and properties of the rays; and the third contains very useful information upon gas tubes and Coolidge tubes. Perhaps in a future edition the author will amplify this outline. There is such an accumulation of radiological data to which medical men may want to turn that we think more categorical information could usefully be introduced into this excellent little book.

HIGH FREQUENCY IN OTO-RHINO-LARYNGOLOGY.

La Haute Fréquence en Oto-Rhino-Laryngologie. By LEROUX-ROBERT, late Assistant in Oto-Rhino-Laryngology at the Salpêtrière. With a Preface by Professeur D'ARSONVAL. Paris: Masson et Cie. 1925. Pp. 166. Fr.15.

THE results of surgical diathermy, or diathermo-coagulation, are well known to laryngologists in this country; indeed, of its effects in cancer of the pharynx, Dr. Leroux-Robert remarks that "the English authors are very convinced, the French authors more reserved." Of this use of high-frequency currents the author of this little book gives a good description; he lays stress on the absence of cicatricial contraction, and recommends employment of this method for many conditions beside malignant growths, and especially for stenosis and contracted cicatrices. Thus, he considers it a particularly suitable method for the treatment of synechiæ in the nasal fossæ, for stenosis of the anterior nares, congenital occlusion of the choana, and for cicatricial contraction of the palate and fauces. Far less convincing is his recommendation of the method in the treatment of obstruction of the Eustachian tube, of stenosis of the larynx, and of multiple laryngeal papilloma after thyrotomy. There is a short account of the use of sparking currents, or fulguration, but the greater part of the remainder of the book deals with medical or diffuse diathermy, and the application of high-frequency discharge from vacuum electrodes, the so-called "effluve" or "violet ray" applications. The author uses the former for chronic and tuberculous laryngitis, and for middle-ear catarrh; and the latter for a large variety of affections, including lupus, eczema, and cutaneous nasal troubles, hypertrophic rhinitis, and ozæna, migraine and sinusitis, tonsillitis, middle-ear catarrh, oto-sclerosis, tinnitus, and vertigo. The use of this form of high-frequency current is obviously only on its trial, and it may be said with certainty that it will not be found to cure or relieve all these conditions. Dr. Leroux-Roberts would doubtless agree to this, and he deserves credit for experimenting in a method which may prove fruitful in some directions. But it would have been better if he had been more exact in the statement of results in this new field, and had given statistics of all cases treated instead of merely describing a few selected cases. He is most enthusiastic on the treatment by "effluve" of ozæna, of which he states that the fœtor disappears, and that no other treatment appears to be so efficacious; and of tinnitus he concludes that "darsonvalisation ought to be tried in all cases with a very great prospect of improvement or cure."

The book includes observations of other workers, the references being given in footnotes; it is written with the enthusiasm of a pioneer, and will be of interest and assistance to those wishing to experiment with the application of the different forms of high-frequency currents to various diseases of the nose, throat, and ear.

EPITHELIOMA OF THE SUPERIOR MAXILLA.

Traitement des Épithéliomas du Maxillaire Supérieur par l'Association Chirurgie-Curiethérapie. Par le Dr. G. VERGER, ancien interne des Hôpitaux de Paris. Paris: Gaston Doin et Cie. 1925. Pp. 204. Fr.22.

THIS monograph deals entirely with epitheliomatous tumours involving the superior maxilla, and with their treatment by a combination of surgery and radium. A description of the pathological anatomy of these tumours is followed by a discussion of their treatment by pure surgery and by radium without operation, and the conclusion is reached that neither method is effective when used alone. The author then describes in detail the surgical technique of A. Hautant and O. Monod, followed by their method of applying radium to the cavity which has been left. This method has been followed in all cases treated at the Institut Curie. In eight cases where the growth was limited to the superior maxilla and the ethmoid, five remained well after periods varying between two and four and a half years. Where a growth is more extensive such good results cannot, of course, be expected, but the author still regards them as encouraging. The author concludes with a description of 43 cases of various types, the value of which is enhanced by the fact that in every instance they have been followed up for considerable periods after operation.

DESIGN AND COMPOSITION IN LINE FORM AND MASS.

By FREDERICK J. GLASS. London: University of London Press, Ltd. 1925. Pp. 175. 10*s.* 6*d.*

THIS is a very interesting book; while, incidentally, it is full of exact instruction for craftsmen, the author's general conclusions are wide, constituting almost a philosophy of æsthetics. There is nothing perhaps in one of the most important chapters, that on landscape composition, which is new, but what may be termed the laws of picture-making, as applied to landscape, are thoroughly well expressed, and their practical value can be apprehended. It is, as the author says, dangerous to formulate rules in art, but despite this there are certain rules of which all those who practise the art of landscape painting ought to be aware. Certainly let those rules be broken for good reasons, and the more sincere and more experienced the painter the more often will he be able to disregard the very existence of rules; but lawless pictures from fervent and learned hands are the finished expression of composition, and not to be confused with the anarchistic messes of those who break rules out of ignorance or insolence. We recommend this book to those of our readers who have found in drawing not only a pleasant recreation but more than occasionally a useful adjuvant to medical studies.

BABIES.

By A. G. G. THOMPSON, M.A., M.D., D.P.H. London: Humphrey Milford, Oxford University Press. 1925. Pp. 32. 1*s.*

ADVICE offered to those untrained in precise or accurate thinking should, above all things, be definite. In this respect Dr. Thompson's little book for the young mother is one of the best we have seen. His style is racy and original and his conclusions are clear-cut. Regularity for both mother and child is emphasised as the keynote of good management, and some sound advice is included as to the advantages of proper organisation in running the home. For the expectant mother good food is broadly described as being fresh food as opposed to that which is tinned, bottled, or preserved. As to the food and clothing of the baby, Dr. Thompson lays the greatest stress upon the infant's own behaviour, which will indicate both how much food and how much clothing are required; he holds that the infant may be relied upon to point out clearly any errors in these matters, but it cannot always be easy to understand the infant's diagnosis or interpretation of symptoms. Dr. Thompson has a particular dislike to the use of biscuits and cakes, which he forbids alike to the expectant mother, the baby, and the older child; milk puddings, he considers, should be postponed until the child is 2 years old, though suet puddings are well liked and digested at 18 months. More than once in the book mothers are warned against resorting to medicine as a cure for the ills of infancy. In cases of digestive trouble, "medicines should come last, not first"; for guarding against colds, "fresh air is the only real chest strengthener and lung tonic"; in connexion with constipation, "the practice of giving a dose of castor oil or any other form of aperient regularly once a week, whether there is any bowel irregularity or not, has nothing whatever to recommend it." A specially useful paragraph is one giving careful directions as to the proper way of blowing the nose, and the damage to the ear-drum which may result from careless nose-blowing of a little child with a cold. The instruction on care of the ears is also valuable. Not all doctors will agree with the statement that a baby's mouth should be cleaned out with a piece of soft, clean rag dipped in warm water; but this is an isolated piece of controversial advice amongst a wealth of orthodox wisdom.

The book may be recommended to mothers as a guide to keeping their babies healthy.

JOURNALS.

Quarterly Journal of Medicine.—The October number contains the following articles: Intestinal Diverticula, by E. I. Spriggs and O. A. Marxer. The appearances of intestinal diverticula, as shown by X ray photographs after an opaque meal, are illustrated by a series of nine plates. In 1000 consecutive X ray examinations on the alimentary tract, intestinal diverticula were found in 143 patients. They are more common in the large than in the small intestine, but may occur in any portion of the latter. Treatment is usually efficacious if directed to the lubrication and efficient action of the bowels, and to improvement in the general health of the patient.—The Relative Prevalence of So-called Endocarditis Lenta Before and After the War: A Survey of 195 Cases, by Gladys C. Wauchope. The conclusions drawn from this article are based on a study of the incidence of endocarditis lenta amongst patients at the London Hospital during the years 1907 to 1924. 195 such cases were recorded, of which 125 came to autopsy. There was found to be a considerable increase in the incidence of this disease in males after the war, the maximum number being observed in the year 1922. In females such a post-war rise was not noted, and the increased rate in the male sex was due to cases occurring amongst ex-soldiers.—The Clinical Syndrome of Thrombosis of the Coronary Arteries, by J. W. McNee. Thrombosis of a large branch of the coronary arteries is not necessarily immediately fatal; in fact, the patient may survive for many years. The author observed three cases of this nature in Baltimore, and a clinical description is given of the main features of the disease. Various references to the American literature dealing with coronary thrombosis are included, and the article is illustrated by two plates showing the macroscopic and microscopic appearances of the heart.—The Excretion of Chlorides by the Healthy and Diseased Kidney, by O. L. V. de Wesselow. The capacity of the kidney for chloride concentration was investigated in a series of healthy individuals and in certain cases of nephritis. It is suggested that there are two groups of cases of nephritis with œdema. In one, the typical parenchymatous nephritis, the chloride plasma content is low, but the œdema fluid is rich in chlorides. The water and chloride pass quickly from the blood to the tissues owing to abnormal capillary permeability, and the œdema is of extra-renal origin. In the other group, which includes acute nephritis, pre-eclampsia, and some cases of prolonged nephritis in which there is œdema without effusion into the serous sacs, the œdema is of renal origin and secondary to failure of water excretion.—Some Observations on the Action of Belladonna and Neutral Fats on the Acidity of the Stomach Contents, by W. Morrell Roberts. By means of the fractional method of gastric analysis it was found that the chief effect of the administration of atropine and belladonna in cases of hypersecretion is to lower acidity by relaxing the pylorus and increasing the normal duodenal regurgitation and rate of stomach emptying. Oil appears to have an opposite effect, delaying the rate of stomach emptying and inhibiting duodenal regurgitation. There is, therefore, a tendency for gastric acidity to rise, and some evidence was also obtained of increased gastric secretion. These changes were not usually found until late in digestion, and after the period at which the one hour test-meal would be withdrawn.—On Sulphæmoglobinæmia, by Lawrence P. Garrod. Two cases of this disease are described, in both of which Mackenzie Wallis's nitroso-bacillus was obtained in culture from the stools. Treatment by large doses of an autogenous vaccine resulted in recovery in each instance, after which the organism could no longer be found in the stools.—The Clinical Aspect of Bundle Branch Block, by John Cowan and J. Crighton Bramwell. A series of 24 cases of bundle branch block are recorded, in all but one of which the right branch of the bundle was affected. The lesion is comparatively rare before the age of 40, and the onset is usually insidious with symptoms of heart failure. Once established it is generally permanent, although it has been noted as a transitory phenomenon. Bundle branch block can only be recognised by means of an electrocardiogram. Post mortem the lesion usually found is a fibrosis resulting from a diminished blood-supply. More rarely it follows an infective process, and the relative preponderance of lesions affecting the right bundle may be due to differences in the blood-supply on the two sides. The right branch of the bundle is supplied by a specific branch of the left coronary artery, which is frequently degenerate, whereas the left branch receives vessels from both of the coronary arteries. The article is illustrated by a series of electrocardiograms.

Biochemical Journal. Vol. XIX., No. 5. 1925.—Among the articles in this issue are many papers of interest to the general medical reader. In a Note on the Presence of Glutathione in the Corpuscles of Mammalian Blood, H. F. Holden has demonstrated the presence of this body in concentrated protein-free filtrates of mammalian blood. He brings strong evidence to show that the lævorotatory powers of this substance probably account for the experimental observations of L. B. Winter and W. Smith. Holden states that the cause of the difference between the rotatory and reducing powers of blood is probably not due to the presence of an unstable sugar, but to this body.—J. A. Milroy has described a method for estimating the blood-sugar by a simple technique involving the use of one of the nitro-anthraquinonesulphonic acids.—The effects of X rays upon normal rats and rats immune to Jensen's rat sarcoma has been studied by E. C. Dodds, W. Lawson, and J. C. Mottram. It was found that there were very marked differences in the response of these two groups of animals.—O. Rosenheim and J. C. Drummond describe further developments of their work upon the colour secretions of cod-liver oil. They state that if the oil be shaken up with arsenic chloride a blue colour results. The chromogenic substance is intimately associated with the vitamin A content, since inactive oils do not give the reaction.—An ingenious apparatus for grinding tissues anaerobically is described by W. A. Roach.—Sir Frederick Gowland Hopkins has written a very complete summary of the influence of glutathione in the oxidation of fats and proteins. The author states that his article must be regarded as a "prolegomenon to publications from this laboratory which will appear in the near future"; his communication is of the utmost importance to workers in this field.—C. P. Stewart and A. C. White call attention to the unsatisfactory position of the subject of blood fat from an experimental point of view. They have elaborated certain modifications of methods of estimation which they claim to overcome most difficulties.—F. Dickens, E. C. Dodds, and S. Wright have reopened the question of the ovarian hormone. As they state, very little advance upon methods of preparation has been made since Hermann and Frankel published their work in 1915. In the present paper a workable method of preparation is described, together with observations on the properties of the hormone. It has been shown that the hormone has an inhibiting action upon the effect of insulin.

THE LANCET.

LONDON: SATURDAY, DECEMBER 19, 1925.

REMOVAL OF NAMES FROM THE MEDICAL REGISTER: THE LEGAL POSITION.

Classical scholars have written their theses on the civic effect and meaning of *infamia* in Roman times. Doubtless, after another 2000 years some antiquary will be writing of the professional meaning of "infamous conduct" in our Medical Acts to-day. Meanwhile, it may be convenient to recapitulate the legal authorities which bear upon the action of the General Medical Council in erasing names from the Register under the provisions of Section 29 of the Act of 1858, for it is clear that many who have been criticising the action of the Council recently have done so without information. The language of Section 29 is familiar and so is the dependent course of events. If a registered medical practitioner is convicted of felony or misdemeanour, "or shall after due inquiry be judged by the General Council to have been guilty of infamous conduct in any professional respect," the Council may, "if they see fit," direct the erasure of his name.

The first remark to be made is that the Medical Act sets up a special statutory tribunal which is not part of the ordinary judicial system of the country, but which is to apply professional standards of the nature of which it is aware and the law courts are not. The tribunal is quasi-judicial. Provided that there has been due inquiry of a bona-fide kind, the law courts have no jurisdiction to review its decisions. Thus, in 1863, in the case of S. La'Mert,[1] a name was removed from the Register after an inquiry into charges connected with the publication of a treatise on venereal disease, and the courts refused to interfere. The Council had formulated its accusation, had communicated it to La'Mert, had received his explanation, and had given him an opportunity to be heard in his defence, though not by counsel. La'Mert moved the Court of Queen's Bench for a rule calling on the Council to show cause why a mandamus should not issue to command them to restore his name to the Register. This was the occasion on which Chief Justice Cockburn laid down the principle that under Section 29 the Medical Council are sole judges of whether a practitioner has been guilty of infamous conduct or not. "This Court," he said, "has no more power to review that decision than they would have (in the present mode of proceeding) of determining whether the facts had justified a conviction for felony or misdemeanour under the first branch of the section. The Council have found the applicant guilty after due inquiry, and, *whether the facts justified the finding or not,* the Council is the tribunal to whom the Legislature has left the decision as being the best judges in the matter. This Court cannot interfere." That was definite enough, but the same decision was enunciated afresh in 1889 in the case of Henry Arthur Allbutt (23 Q.B.D. 400), who similarly sought a mandamus to compel the restoration of his name after erasure. Allbutt fitted a second string to his bow. He sued the Council for libel over the publication of their findings in his case. Baron Pollock said the Council had sole jurisdiction under the Act and his Court was powerless to review the decision. The Court of Appeal agreed and reaffirmed what Chief Justice Cockburn had said in La'Mert's case. The claim for libel was equally unsuccessful. "It was admitted," said Lord Justice Lopes, "that the report of the finding was truthful, accurate, and honestly published bona fide and without malice, not an ex parte report, but a report of facts which had been finally ascertained and adjudicated upon." If the mere fact of erasure had been stated, it would clearly have been privileged; the privilege could not be lost merely because the reason for the erasure was given. Thus, in 1889 the finality of the Council's decisions under Section 29 was completely established; it has never since been judicially questioned.

Has a practitioner whose name has been erased no remedy then? The answer is "No, not unless there has been bias on the part of the tribunal or some irregularity of procedure," as for example, if the Council omitted to frame charges, or to inform the practitioner of what was alleged against him, or to give him a chance to reply. As to bias, a person who has a pecuniary interest in the result of an accusation cannot adjudicate upon it, and it is a well-founded legal principle that public policy and natural justice forbid an accuser to be also a judge. Light was thrown upon this point in J. F. Leeson's case (1889, 43 Ch. D. 366), where Lord Justice Bowen said the crucial question was whether in substance or in fact one of the judges has actually been an accuser. This dictum has since been interpreted by Lord Esher ([1894] 1 Q.B. p. 759) as meaning that a judge's position must be such that in substance and fact he cannot be suspected. Not that any perversely-minded person cannot suspect him, but that he must bear such a relation to the matter that he cannot reasonably be suspected of being biased. This was not quite the same view as Lord Justice Fry had taken in Leeson's case, that learned judge having never lost an opportunity of advancing impeccable moral standards. The principle has been more broadly stated: "It is highly desirable that justice should be administered by persons who cannot be suspected of improper motives" (Mellor, J., in Regina *v.* Allan, 4 B. & S. at p. 926). Or as Lord Reading, and more recently Lord Hewart, put it, it is not enough that justice should be done; it is essential that it should seem to be done. The question of bias in members of the tribunal arose in Leeson's case from the membership by two of the Council of the Medical Defence Union and this was the main point in Allinson *v.* General Council of Medical Education and Registration ([1894] 1 Q.B. 750). T. R. Allinson advertised himself in a flagrant manner. He inserted in newspapers answers to real or imaginary correspondents as to the treatment of complaints and he gave his own name and address, his fees, his writings, and their prices. He also systematically vilified his own profession—"professional poisoners, for I can call doctors by no truer name." Here is a sample of Allinson's announcements: "Send a postal order for 5*s.* with a stamped directed envelope, and I will send you private postal advice that will benefit you." The Council very properly resolved to remove him from the Register. He applied for an injunction to prevent this, and, when his application failed, went to the Court of Appeal where he failed again. His material ground was bias on the part of the tribunal. The late Sir George Philipson, who represented Durham University on the General Medical Council, and who had been one of those who adjudicated in the case, had also been a vice-president of the Medical Defence Union which had instituted the proceedings against Allinson. Sir George Philipson, as a vice-president, was an ex-officio member of the committee of the Union, but did not attend its meetings and was unaware of the proceedings. He had actually resigned from the Union at the material date in the case, though technically his resignation did not take effect till afterwards. The Court of Appeal held that he was not disqualified as an adjudicator, though in Leeson's case Lord Justice Bowen had said it was undesirable that members of the Council who adjudicated should be subscribers to the society which instituted and conducted the proceedings.

---

[1] Law Journal Reports, xxxiii., Q.B. 69.

If a practitioner whose name has been removed from the Register has any grounds for alleging that the tribunal was biased or the proceedings irregular, his legal remedy is to apply for an injunction to stay the hands of the General Medical Council or for a mandamus to compel the restoration of his name. In this connexion it may be observed that the Council has no express statutory power to restore a name (except in one particular contingency under Section 14 of the 1858 Act). But it is assumed—no doubt rightly—that any body which exercises functions such as those assigned to the Council can vary or rescind its own decisions. The Council will restore a name in a proper case, but this is not a matter of legal compulsion. Indeed, even if a name has been erased for felony and the conviction is afterwards shown to have been erroneous, there is no power to compel what the Council would doubtless concede, and has in fact conceded.

As is well known, the Privy Council has a general power of supervision over the General Medical Council. But it is not to be supposed that a man whose name has been removed from the Register can appeal with any prospect of success to the Privy Council either in its executive capacity or in its judicial capacity. The Judicial Committee of the Privy Council has high authority as an appellate tribunal, and His Majesty under an Act of 1833 has a general power to refer to the Judicial Committee any issue which he may think fit. But it may be taken for granted that, while the Supreme Court refuses to review the decisions of the General Medical Council, the Judicial Committee will never be called upon to act as a Court of Appeal in this respect. The supervisory power which the Privy Council wields over the General Medical Council is to be found in Section 19 of the Medical Act of 1886. That section runs as follows :—

> "If at any time it appears to the Privy Council that the General Council has failed . . . . to exercise any power or perform any duty or do any act or thing vested in or imposed on or authorised to be done by the General Council under the Medical Acts . . . . , the Privy Council may notify their opinion to the General Council ; and if the General Council fail to comply with any directions of the Privy Council relating to such notification, the Privy Council may themselves give effect to such directions, and for that purpose may exercise any power or do any act or thing vested in or authorised to be done by the General Council. . . . ."

This means that, supposing the General Medical Council did not maintain its Register and did not strike off it the names of practitioners who are convicted of felony or are guilty of infamous conduct in a professional respect, the Privy Council might conceivably take over the Register and the power of inquiring into professional misconduct and of removing the names of the guilty. But it does not mean that the Privy Council can meanwhile intervene to say "You shall not inquire into A's case, or you shall re-try B's case, or you shall restore C's name to the Register." The Privy Council might influence the general policy and outlook of the Medical Council by appointing to the latter body from time to time representatives who are known to favour a fresh policy. Or the Government might set up a Committee or a Royal Commission to consider whether the present constitution of the Medical Council is sufficiently elastic or too institutional, and whether the statutory provisions as to maintenance of the Register require modification. But any change would necessitate fresh legislation, and no Government is likely to legislate on such a matter without the full assent of the profession.

Finally, we come to the vexed question "What is 'infamous conduct in any professional respect ?' " Historically, the word infamy has, in English law, meant the condition of being deprived of the rights of citizenship in consequence of conviction for certain crimes. Persons who were in this sense infamous were, until they had served their sentence or been pardoned, disqualified for public appointments or public pensions, and incapable of serving as jurors or sitting in Parliament or giving evidence in a court of law. This last incapacity was removed by the Evidence Act of 1843, and the expression "infamous crime" survived as a sort of synonym for the crime specially known as abominable. The expression can be seen as late as 1861 in Section 46 of the Larceny Act of that year (extortion under threat to accuse of crime). But when that section was superseded by the Larceny Act of 1916, the words were dropped. The historical associations of the word "infamous" are irrelevant when it is used in Section 29 of the Medical Act, because of that significant addition "in any professional respect" on which the law courts have laid so much stress. Just as under the ancient laws of England, if a citizen committed some anti-social offence he was placed outside the pale of society, so now under the Medical Act, if a registered practitioner commits a grave offence against the rules of his profession he may be placed outside the body of professional men who agree to be bound by those rules. Nor let it be forgotten that it is the British tradition to rely upon each trade or calling or service to maintain its own standards. The Army Act punishes with cashiering officers who behave "in a scandalous manner unbecoming the character of an officer and a gentleman" ; the Naval Discipline Act punishes with dismissal from the service any officer who is guilty of "conduct unbecoming the character of an officer." These robust phrases, deliberately vague, depend for their interpretation not upon the law courts, but upon courts martial consisting of the accused man's brother-officers. The law courts have, as Sir Donald MacAlister reminded us, given help in interpreting "infamous conduct in any professional respect." Lord Justice Lopes, in Allinson's case ([1894] 1 Q.B. at p. 763), recalls how he, Lord Esher, and Lord Justice Davey prepared what is now the classic definition : "If it is shown that a medical man in the pursuit of his profession has done something with regard to it which would be reasonably regarded as disgraceful or dishonourable by his professional brethren of good repute and competency," then the Council can say he has been guilty of infamous conduct in a professional respect. The question, as Lord Esher said earlier in the same case, is not whether what a doctor has done would be infamous for anyone else to do, but whether it is infamous for a medical man to do. An act done by a medical man may be infamous, though the same act done by anyone else would not be infamous ; on the other hand, an act not done "in any professional respect" is not within the section.

Times change and standards alter with them. The Council can, if it likes, decide that methods of advertisement hitherto considered objectionable shall in future go unpunished or shall even be regarded as consistent with the traditions of an honourable profession. If this position is desired by members of the profession which the Council represents, it will eventually be attained. Pressure may come from within or from without, but the official reply on behalf of the Lord President of the Privy Council to a question in the House of Commons on Dec. 8th does not indicate official dissatisfaction. That reply ran—"The Medical Council, since its creation in 1858, has performed the duties entrusted to it without serious criticism, and as at present advised my noble friend does not think that sufficient reason has been shown for setting up a committee of inquiry." We believe that any clear-headed and unprejudiced member of the public, who should follow, as we have done, the actual proceedings in the disciplinary cases, would agree that the recent outcry against the Council's use of its powers has been unjustifiable. Most of the offenders have not been unduly punished, and the minority, convicted of less serious infractions, have been restored to the Register in generous measure.

◆

PENSIONS FOR SALARIED HOSPITAL STAFFS.

A COMPREHENSIVE and generally acceptable scheme of pensions for the salaried officers of voluntary hospitals is long overdue. King Edward's Fund has been giving serious, if more or less intermittent, attention to the subject ever since 1914, and had it not been for the disturbing effects of the war there might have been some definite outcome of the pains it has devoted to the subject. The growing need for action is emphasised by the publication last week of a memorandum, summarised on another page, setting out a draft scheme of pensions prepared by a conference representing the King's Fund, the British Hospitals Association, the Incorporated Association of Hospital Officers, and the College of Nursing. Generally speaking, the scheme follows the lines laid down by the committee of the King's Fund, over which Mr. W. J. H. WHITTALL, F.A.I., presided, but the conference carefully guards itself from any expression of opinion upon the merits of the proposals. It is naturally sympathetic to the principle of a pension scheme, but leaves the details to the consideration and criticism of the hospitals. For many reasons it has hitherto been found difficult to induce English hospitals to take concerted action on matters of general moment to them, and it would be unduly sanguine to expect immediate action upon these revived proposals. Every year, however, the subject presses more urgently, and the growing scarcity of nurses makes it more than ever important that a settlement should be reached without serious further delay.

The existing situation is at once unbusinesslike and chaotic. An official may be pensioned comparatively early or decidedly late; the amount of the pension is dependent upon the views of some committee or board of governors, and an official who leaves one hospital for another loses all claim upon his late employers and may not live long enough to establish one upon the new. What is needed is a system which attaches pension rights to the vocation and not to the service of a given institution. To nurses this is of almost vital importance, since most of those who begin their careers in hospitals end them in some other milieu. The pay of nurses, although somewhat improved, is still, and is, unhappily, likely to remain, inadequate to the provision of any real protection in old age. It is unreasonable to expect a constant flow of the right type of probationer in response to no better prospect than poverty when hard work is no longer possible. To talk to her about the sacredness of her calling and the glory of self-sacrifice in such circumstances is a mockery. Under the scheme now set out the nurse would take her policy with her, as would the secretary or the accountant or any other hospital official. The Federated Superannuation Scheme for Universities is taken as the model, and under it the hospitals would contribute 10 per cent. of salary and emoluments and the beneficiaries 5 per cent. The whole of the salaried staff, administrative, clerical, and dispensing, as well as the nurses, would be included, though the probationer nurses would not come in until the end of their first year. There would be a choice among three types of policy—a fixed rate of annuity at the retiring age or a sum of money at previous death; deferred annuities with eturn of premiums on premature withdrawal or death; and deferred annuities without return of premiums. Nurses would become pensionable at 55, which may be a reasonable age for the purpose, though we are not certain of this. But would it be equally reasonable to pension secretaries and other officers at 60 as the scheme proposes? That is earlier than the Civil Service limit, and in these days the number of men who remain active and full of work and initiative at long after 60 is far greater than ever it was. To put back the age three or even five years would not be unfair to the beneficiaries, would substantially strengthen the plan, and would ensure a larger yield. The extent to which operative effect is given to the proposals depends upon the hospitals—not so much upon the goodwill of the governors, which may be taken for granted, as upon their finances. An addition of 10 per cent. to the amount paid in salaries would often be serious, but sooner or later it will have to be done, and we are not entitled to exploit long and willing service of a type in which there is nearly always a basis of altruism. But it would be of little use for a hospital here and there to come in. What is needed is the all-round adoption of this or some closely similar scheme after it has undergone the criticism of hospital authorities generally.

FATIGUE AND INFECTION.

THERE is a general impression that resistance to infection is associated with the bodily state which comes from a good intake of food combined with a moderate amount of muscular work, and Dr. LEONARD HILL has preached pretty convincingly that the beneficial effects of fresh air are due to, or at least connected with, the increase of general metabolism which is produced. Whether this is really so is one of the most important problems which the economics of dietetics has to solve, though the smallness of the quantities of food and activity which have to be measured makes it unlikely that an answer will easily be found to the question whether it pays people to eat the little excess over their minimum requirements which they generally do on an unrestricted diet. Less food and less exercise cost less; the habits of mankind suggest that they are more expensive in the long run. Similarly common opinion reckons that excessive fatigue and a sedentary life both favour infection, and the latter idea, at least if it is practised without a correspondingly meagre diet, is backed by the practice of some insurance companies whose experience has taught them to look with suspicion on those who are too heavy for their height. Some experimental observations made by the late Dr. R. A. SPAETH [1] do something to elucidate these problems. He and his colleagues had previously obtained the seemingly paradoxical result that rats and guinea-pigs, forced to take exercise to exhaustion, were more resistant to pneumococcal infection than normal animals. He now shows that rats which are kept "in the pink" by living in cages where they can and do take spontaneous daily exercise for their own enjoyment are rather less resistant than the controls despite their apparently splendid physical condition. He then points out that guinea-pigs which are starved till they have lost about as much weight as they would if exercised to exhaustion are more resistant than normal, and suggests that the influence of exhausting exercise on infection is related to the anabolic restoration of weight rather than to the fatigue itself or to any products of fatigue. This is supported by the observation that fatigue does not increase resistance unless the animal is allowed to eat immediately afterwards; this it does voraciously. The experiments as a whole afford an interesting commentary on the proposition that using the body promotes resistance to infection. They need repetition and amplification, and the eating habits of the experimental animals make it difficult to transfer the experience to man who, under civilised conditions at any rate, generally finds that a hearty meal is a mistake when he is very tired. The fact that starvation helps resistance under the conditions of the experiments finds a parallel in the observations[2] of Dr. J. A. ARKWRIGHT and Dr. S. S. ZILVA that similarly reduced animals give a small local inflammatory response to irritants, for infection is dependent on the response of the body as well as on the presence of the parasite. There is something in asceticism which wants analysis.

[2] Jour. of Path. and Bact., 1924, xxvii., 346.

LONDON COUNTY COUNCIL: DEBATE ON ASSESSMENT FOR TUBERCULOSIS TREATMENT.—Dr. Stella Churchill was last week responsible for initiating a prolonged debate at the meeting of the London County Council on the assessment of contributions in respect of residential treatment of tuberculosis. In the course of the debate, it was freely asserted that the Council had no legal right to exact contributions from patients or those legally responsible for them, that only poor and ignorant people consented to payment, and that even where payment was point-blank refused the Council had no power to withhold treatment. The whole subject of assessment has been under review by the Public Health Committee of the Council, who tabled a recommendation that no change be made in the present methods. Dr. Churchill moved as an amendment that "no contributions be required by the Council in respect of residential treatment of tuberculosis under the Council's scheme whether for children or adults," and quoted details of several cases where, she alleged, the assessment had inflicted great hardship on the families concerned. Dr. Alan Randle, in supporting the amendment, declared that the money exacted by the Council might well be left with the families, in order to tide over the difficult period when the breadwinner was in a sanatorium, to relieve the patient of anxiety while undergoing treatment, or to be accumulated for the purchase of nourishment when the patient was discharged and temporarily unable to work. Many patients, he said, insisted on discharging themselves from sanatoriums, against the wishes of the authorities, purely because of anxiety as to their home conditions during their absence. From the Labour benches the threat was made that, unless the Public Health Committee agreed to modify or abolish assessments, the greatest possible publicity would be given to the fact that the Council was powerless to enforce payment. Dr. Churchill's amendment was defeated on a division and the recommendation of the Committee was carried. The present method of assessment will, therefore, continue unchanged.

Annotations.

"Ne quid nimis."

VOLTAIRE AND MEDICINE.

IN a paper on this subject, of which he read the second part before the Section of the History of Medicine of the Royal Society of Medicine last Wednesday, Dr. J. D. Rolleston, the President, discussed Voltaire's relations to individual doctors and the medical profession as a whole, and gave some account of Voltaire's illnesses. Apart from small-pox, influenza, and pneumonia, Voltaire did not appear to have had any acute infectious disease. He was subject to chronic dyspepsia from an early age, and frequently suffered from catarrhal bronchitis, often associated with deafness. His death at the age of 84 was probably due to uræmia following cystitis due to enlargement of the prostate. Throughout his life Voltaire was brought into contact with medical men on many occasions, both professionally and socially, the best known of his medical attendants being Silva, physician to Louis XIV., Boerhaave, and Tronchin. Dr. Rolleston pointed out that the passages in which Voltaire indulged his satirical humour at the expense of the medical profession were few in comparison with those in which he expressed admiration and gratitude, and apart from his stories were mainly to be found in his correspondence where they were not to be taken too seriously. In striking contrast with Molière's works, in none of Voltaire's plays did a doctor figure as one of the *dramatis personæ*, nor were there more than one or two vague references to medical matters in any of them. Voltaire was scathing in his denunciation of quacks and quack remedies, such as "potable gold," the "balm of life," and Arnould's sachets for epilepsy, and vented his ridicule on many superstitions and erroneous doctrines connected with normal and morbid processes. Dr. Rolleston quoted numerous passages from Voltaire's works illustrating his advocacy of inoculation for small-pox, his interest in the history and ravages of syphilis, his attention to other matters connected with public health, his acquaintance with medical jurisprudence, and particularly his sceptical attitude towards historical cases of poisoning and his description of various disease of social importance, such as mental disease, convulsive hysteria at the tombs of saints and ecclesiastics, alcoholism, and the king's evil. His interest in public health was shown not only by his desire to control contagious diseases, such as small-pox by inoculation and syphilis by the formation of an international league—a project not realised till the foundation of the "Union internationale contre le peril vénérien" 150 years later—but also by his allusions to other epidemic diseases, especially plague, typhus, and malaria, his condemnation of the insanitary condition of the Paris hospitals, the abuses connected with the administration of military hospitals, the crowded state of the Paris cemeteries, and the practice of burial in churches, as well as by his proposal to found maternity hospitals for unmarried women. In conclusion, Dr. Rolleston maintained that Voltaire, the founder of modern history and the most representative figure of the eighteenth century, deserved the attention of the medical reader in that he was a powerful advocate of the profession and an uncompromising foe of quackery, and by reason of his keen intellect and wide humanitarianism was well in advance of his time in matters connected with public health, medical jurisprudence, and social medicine.

MALARIA AND PARTURITION.

TWO workers attached to the Sir Alfred Lewis Jones Research Laboratory at Freetown, Sierra Leone, have made the interesting observation[1] that the placental blood of parturient native women is frequently the site of an intense infection with the subtertian malaria parasite—*Plasmodium falciparum.* Dr. Blacklock and Dr. Gordon examined in the course of this study 150 parturient women aged from 15 to 42, and of these 55 proved to be infected; of these only ten showed infection of both peripheral and placental blood; of the remaining 45 the placenta alone was infected. It is probable that in these cases the parasites remain localised to the placenta, but it is a curious and important point that in no child born of a malaria-infected mother were parasites found either in the cord or peripheral blood. The difference between the placental and peripheral incidence of malaria infection is ascribed, in all probability, to a peripheral blood immunity, and therefore, as a source of infection to others, these intensely infected women can be disregarded as a danger. Of the 144 children who were born alive in the series under consideration, 51 were born of malaria-infected mothers, and 13, or 25·5 per cent., died within seven days of birth, a very much higher percentage than of the children born of non-malarious mothers. In spite of this, it is a remarkable fact that no evidence of infection of the children with malaria parasites derived from their mothers could be adduced; a statement which appears to be in opposition to the views of Liemann and Swellengrebel, who record a large number of cases of congenital malaria, and attribute a high proportion of infantile deaths to it. Dr. Blacklock and Dr. Gordon, on the other hand, attribute the ill-effects, undoubtedly produced in the child, to toxic substances absorbed from the intensely infected placenta of the mother and to the interference with the proper nutrition of the fœtus brought about by this parasite. There is no evidence, they think, that there exists any tolerance to malaria on the part of the child, but the absence of parasites in the peripheral blood may be ascribed to freedom from infection, for after the first month of life parasites may be found when the child has had the opportunity of developing fever as the result of bites by infected anophelines.

THE MEDICAL STAFF OF THE PUBLIC HEALTH SERVICE.

PUBLIC health administration leaves a good deal of room for local initiative. In his annual report for 1924 Dr. Ralph M. F. Picken, medical officer of health for Cardiff, points out that the problem of the most effective use of the medical staff in the diverse functions of a modern health department is becoming more and more complicated. He goes on to say that the easiest administrative arrangement is to allocate one or more medical officers to a particular section of the work, but that the effect of such a method is to create water-tight compartments in which the staff are apt to lose the wider outlook. "The more varied the work, the more stimulating and interesting it is." With a view to attaining the highest ultimate efficiency the staff of the Cardiff health department are each employed in as many branches of the work as it is possible to arrange, even at considerable administrative inconvenience. Dr. Picken suggests that the practice of sanitary authorities farming out some of the most important and interesting sections of the clinical work has a paralysing influence on the mental development of the whole-time medical staff, but that at the same time such farming out puts the highest specialist's skill at the disposal of the sanitary authority. In order to remove the drawback mentioned and to retain the interest of the whole-time medical staff, arrangements have been made at Cardiff to associate the assistant medical officers with that part of the clinical work of the institutions which is financed by the corporation. A similar problem crops up with regard to the nursing staff. For example, the tuberculosis officer likes to employ his own nurses and to have as few changes as possible; the school medical officer and the maternity and child welfare medical officer have a similar bent. It must be better, however, for the mental development of the public health nurse (and ultimately for the service) if she has the opportunity of becoming familiar with the work of every department. Many people will therefore agree with Dr. Picken when he says that "the organisation would be improved if it were found administratively convenient to amalgamate the school medical staff and the health visitors as has already been done in the case of the medical staff." In a paper on Coöperation between Public Health Officers and the General Practitioners by Dr. Picken,[1] which appears as an appendix to his report, the opinion is expressed that a bold and comprehensive scheme of coördination is needed to bring these two sections of medical practice into working contact, and that any such scheme should make it as easy as possible for men to transfer themselves from the public health service to general practice, and vice versa, if they find they have chosen the type of work which is not their vocation. Obviously there will always be more heads of departments than there are administrative chiefs, but the arrangements made at Cardiff should enable a man with administrative ability to obtain the experience necessary to qualify him as a medical officer of health of the front rank.

THE DEATH-RATE FROM DIABETES.

IT is still too early in the period of insulin therapy to attempt to predict in any detail what the effect of the use of this substance will have on the death-rate from diabetes. The fact that diabetic coma so far from being inevitably a fatal complication is now so brilliantly treated by insulin will obviously have the immediate effect of reducing the number of deaths reported from diabetes, but it is possible that another effect will be the postponement of the end of a certain number of patients, so that in a few years' time the actual number of deaths from diabetes will show an increase. These and other considerations must therefore be borne in mind in any discussion of this subject, but even so the present death-rates from diabetes in different countries show very marked differences, and in a recent paper[2] Dr. E. P. Joslin has analysed the death-rate from this disease and its complications in Massachusetts, and compared these with corresponding figures for London with very interesting results. He finds, for example, that in 1923 the death-rate from diabetes in London per 100,000 was 9·51 and in Massachusetts 21·4, and, further, the increase in the diabetic death-rate from 1880 to 1923 in London was really threefold, while in Massachusetts it was fourfold. He therefore maintains that in that State there is an acute diabetic problem which must be solved along the lines of preventive medicine. Further analysis of the figures for these two population groups shows that the increase in Massachusetts is particularly found in the older decades, and Dr. Joslin urges that one of the principal prophylactic measures is to get patients to eat less and take more exercise in order to avoid obesity. The State Department of Health for Massachusetts has definitely entered upon a campaign to eradicate diabetes, which is of great interest, since here it is dealing both with a non-infectious disease and with one which is not particularly concerned with the young. One of the measures adopted has been the distribution of a bottle of "doctor's emergency insulin" for the doctor's bag, made possible by the generosity of Mr. John D. Rockefeller, jun. With this bottle is sent careful instructions for the treatment of diabetic coma which is still the chief cause of death in diabetes, and an interesting feature of these instructions is the scheme suggested for estimating the amount of insulin required in any particular case. This is based upon the probable duration of life without insulin as estimated by full clinical considerations. If this is in the neighbourhood of 24 hours, 20 units of insulin are given, and repeated every hour until the clinical improvement and sugar in the urine and blood is approaching normal. If the patient's expectation is 12 hours, 40 units would be used, and if death appears to be imminent, 40 units of insulin can be given every 15 minutes. The other complications of diabetes which must be attacked—for it is a well-known clinical fact that very few diabetics die of uncomplicated diabetes—include cardio-renal affections, gangrene, tuberculosis, and carbuncles, and in all of these cases Dr. Joslin hopes for a reduction of the death-rate when accurate dietetic treatment and the necessary medical and surgical coöperation in certain of the conditions are satisfactorily established, which state of affairs, he hints, has not yet been attained.

RESIDENCE AND DISEASE.

AN inquiry of some interest carried on among University students in America has just been published.[1] It was undertaken to obtain some measure of the value of urban health practices. The measure used is the past history of diseases among the students, classified according to the size of the community in which childhood was spent. Every care was taken to ensure that the information gathered was as accurate as possible. The communities were grouped as (*a*) rural, (*b*) villages of 50 to 1000 population, (*c*) small towns of 1000 to 5000, (*d*) small cities of 10,000 to 50,000, and (*e*) large cities of 50,000 and over. In a previous communication[2] the authors reported finding physical defects high in (*a*), (*b*) and (*d*), low in (*c*), but lowest in (*e*). Apparently classification of mortality and morbidity records may be vitiated if all populations below 25,000 are considered rural and all above as urban. Records were obtained of 5031 students, of whom 3478 were men and 1553 were women. Seventeen diseases, including all the infectious fevers of childhood, were prevalent enough to classify in the table here reproduced:—

Table showing Percentages, according to Residence Groups, of 3478 University Men, giving Histories of Certain Diseases.

Past diseases.	Rural (358)*	Villages (299)*	Towns (605)*	Cities.		Total (3478)*
				Small (379)*	Large (1837)*	
Measles.. ..	62·9	*88·0*	62·0	69·1	55·8	61·8
Mumps ..	46·4	*65·2*	47·6	53·8	45·4	48·5
Diphtheria ..	4·5	6·7	5·1	*10·8*	9·6	8·2
Scarlet fever..	12·6	14·1	*15·0*	10·6	14·5	13·9
Chicken-pox..	24·0	*45·8*	38·2	40·1	39·6	38·4
Small-pox ..	*11·2*	10·7	10·1	8·7	7·3	8·6
Whooping-cough ..	31·3	*39·1*	34·4	32·7	32·8	33·5
Influenza ..	35·5	*42·2*	35·1	34·1	21·1	28·2
Pneumonia ..	*12·6*	9·7	11·2	10·3	12·1	11·6
Pleurisy ..	*5·9*	3·7	3·6	4·8	3·2	3·7

Chorea	0·3	0·0	0·5	0·5	*0·8*	0·6
Nervous break-down.. ..	1·7	*2·0*	1·0	0·5	0·6	0·9
Total ..	287·0	368·5	301·7	326·4	279·1	296·6

* The figures in brackets indicate the number of students in each group.

The figures in italic represent the highest percentage for each disease.

The female records, although rather few for analysis, support the tendencies of the male records. The order for all diseases, or for the infectious diseases alone, is the same: cities best, followed by rural, towns, and small cities, with villages worst. Thus cities stand out favourably both for histories of diseases and physical defects, and small cities come out unfavourably by both measures. The order of importance of the diseases is interesting with measles leading easily, and mumps a good second. In this country typhoid and small-pox would probably not appear in such histories. The percentage which is highest for each disease is italicised in the table. Pneumonia is curiously high in rural, with great cities a close second. Villages claim far too many firsts, but are lowest for pneumonia. Some evidence may be found in these studies to support the thought that, at any rate in America, modern hygiene is capable of making the populations of great cities the most healthy and vigorous part of the community, even in advance of the oft and frequently extolled rural yeoman class. The records, however, on which the evidence is based, refer only to a favoured portion of the population in each residence group, and not to the total populations; they are evidence of what might be done for the whole, rather than of what is being done.

THE MEDICAL DIRECTORY.

THE eighty-second annual issue of the Medical Directory, which has just appeared,[1] does not differ materially from its predecessor except that it has been brought scrupulously up to date. A single misprint of a Swiss health resort has escaped the watchful eye of the press-reader on both occasions—that is the only blemish we have noticed. The numerical summary of the medical profession shows an increase of 1802 on the previous year in the total number of names contained in the Directory, being an addition of 3·6 per cent., well in excess of the annual increment in the population of the British Isles. This increase is distributed fairly evenly over six sections of the Directory, only the Services showing a small diminution. In the section of useful information preceding the Directory appears a monograph on the spas and climatic health resorts of Great Britain and Ireland. The whole section has been recast and partly rewritten, and is accompanied by a number of illustrations. The list of certified masseurs belonging to the British Association, introduced last year, has increased in length, and the lists of personnel of the Ministry of Health, Medical Research Council, and Central Midwives Board have been shifted into the middle of the volume between London and the Provinces. The new issue will take its place on the shelf as an indispensable book of reference.

MASSAGE IN THE TREATMENT OF MIDDLE-EAR DEAFNESS.

IT would seem reasonable to expect good results from massage in certain diseases of the middle ear, especially in cases of recent exudation and of chronic adhesions and thickening of the drum membrane and even, it might be, in the earliest stages of otosclerosis. Many years ago Delstanche, of Brussels, designed an apparatus for this purpose, consisting of a small hand pump with a length of flexible tubing attached to a terminal fitting into the external auditory meatus; by alternately rarefying and compressing the air in the meatus the membrana tympani is moved outwards and inwards. For this work he was awarded the Lenval Prize for having designed the best instrument for the relief of deafness. This method, called pneumo-massage, has been modified by attaching the pump to an electric motor, or to a geared-up machine worked by hand, so that the rapidity of the movement may be greatly increased and, judging by the numerous instruments of this kind on the market, this form of treatment has been very extensively used. But, unfortunately, the movement may only affect the more mobile portions of the drum membrane, while having no effect on adhesions, and there is no proof that any motion is conveyed to the chain of ossicles, especially when unduly rigid or fixed by pathological changes. Sometimes tinnitus is diminished, the sense of weight or oppression relieved, and even the hearing temporarily improved; but this form of massage cannot be said to have added much to our power of treating chronic deafness. Manual massage of the side of the neck and the upper cervical spine has also been used, and the Swedish exponents of massage have employed their methods for the relief of aural disease. In Vienna Dr. Michael Braun [1] is enthusiastic on the treatment of progressive deafness by a method of manual massage which he has designed; this consists in massage of the nares, nasopharynx, and Eustachian tubes with wool-tipped probes, and of the auricle, tragus, and external meatus with the fingers. His method of Eustachian massage has received the endorsement of Prof. E. Urbantschitsch, and he claims to have obtained improvement of hearing and relief of tinnitus in some very advanced cases of middle-ear deafness.

ARSENIC IN APPLES.

IN 1892 Miss Eleanor Ormerod ("Text-Book of Agricultural Entomology") referred to "the method of spraying caterpillar-infected leafage with Paris green which has long been found serviceable in the United States and Canada," adding that it "should never be applied to fruit or to vegetables that are used for food." The Ministry of Agriculture and Fisheries (Leaflet 352) advises the use of "lead arsenate either just before or just after the blossoming period (on no account when the flowers are open)." That such compounds well distributed over foliage would discourage the hardiest leaf-eating insect seems hardly open to discussion, but the use of such very poisonous substances in the preparation of potential food-products must introduce grave risks when the spraying is done after the blossoming period. To depend upon wind and rain for the removal from the surface of apples of the arsenical compound is surely light hearted, and there is the further danger of diffusion into the substance of the fruit. The recent prosecutions of Hampstead tradesmen for selling Jonathan apples containing from 1/30 to 1/15 gr. of arsenic in a pound show that the risk is a real one. Out of 16 or 17 samples purchased five contained 1/100 gr. or upwards of arsenic. It appears that the prosecutions were undertaken as the result of a complaint of illness after eating apples and not because the medical officer or public analyst were seeking new activities. These cases raise again in an acute form the ever-recurring question of the "doping" of foods. A normal sounding meal may easily contain quite considerable doses of boric, benzoic, salicylic, and sulphurous acids and synthetic dyes in the earlier courses and the drinks, and now the dessert may contribute its quota of arsenic. It is urged in the case of arsenical apples, as in all such cases, that the amount is small—well below the maximum dose. Further, it is pointed out that by peeling the apples all danger is avoided. There are many people who believe that the full flavour of an apple is not to be obtained when it is peeled, and there are many boys and even adults who, given opportunity, might easily take, if not a lethal dose, sufficient to cause serious illness, as, in fact, people in Hampstead appear to have done. Two other aspects of the case are worthy of consideration. The unhappy family doctor will have new perplexities in diagnosis and the poisoner will be able more effectively to raise the defence of arsenic in apples than was a well-known advocate 80 years ago who attempted to prove that his client's victim had been killed by natural poison in apple pips. On all grounds the presence of arsenic in apples is to be discouraged, and it is to be hoped that the appropriate Ministries in apple-growing and exporting countries will take measures to reassure the public. The apple is a delightful and important article of food, and the fruit trade between this country and the United States is large. The Minister of Agriculture and Fisheries has stated in the House of Commons that the danger of poisoning arising from the spraying of apple trees is negligible. It may be so in English apples.

THE IRISH CENSUSES OF 1926.

AN Irish census, writes our Dublin correspondent, was due to have been taken in 1921, but on account of the disturbed state of the country at the time it was thought wise to postpone the attempt to take it. With the boundary of the Free State jurisdiction unsettled, no step was taken by either the Free State Government or the Government of Northern Ireland until recently. Both Governments have now decided to take censuses next April, and it is stated that the officials in charge of the census in the two areas have agreed to proceed on similar lines. If this intention is carried out, then the joint result will practically be a census of all Ireland. At a recent meeting of the Statistical and Social Inquiry Society of Ireland, Prof. C. H. Oldham, President, delivered an address on Reform of the Irish Census of Population. He pleaded for a simplification of the census, and suggested that some of the information heretofore collected in the census returns should be obtained otherwise. Statistics in regard to agriculture and land might more properly be collected by the Department of Agriculture, and those in regard to education by the Department of Education. He urged also that the census of religious professions should also be omitted or the enumeration left to the several churches. It is to be noted that neither the English nor the Scottish census has, in the past, collected any of these three classes of figures. Prof. Oldham thought also that the informative value of the census would be much increased if comparisons with other countries were widely given. In the discussion which followed Prof. Oldham's paper it was pointed out that the statistics collected in previous censuses as to the number of sick on census night were so fallacious as to be worse than useless. Moreover, the grouping of diseases was meaningless. The Department of Local Government and Public Health, which is charged with the duty of carrying out the census in the Free State, has invited suggestions from learned bodies and from persons interested in statistics.

KING EDWARD'S HOSPITAL FUND.

AT a meeting of the President and Council of this Fund it was announced by the Prince of Wales that the amount of the ordinary distribution had been raised from £235,000 to £245,000, apart from the grants out of the Wells legacies, which accounted for an additional £57,000 this year. The area covered by the Fund is now 380 square miles, and the number of hospitals helped is now 133. The fact that the hospitals as a whole show an annual surplus instead of the large deficit which caused such anxiety five years ago, is a cause for legitimate satisfaction. Continuous effort is, however, essential, inasmuch as every important advance in medical science and every additional bed involves increased expenditure.

WE regret to announce the death at his London home in his eighty-fourth year of Sir Richard Douglas Powell, Physician-in-Ordinary to the King and consulting physician to the Middlesex and Brompton Hospitals.

Colonel Percy S. Lelean, R.A.M.C. (retd.), Home Office Inspector under the Cruelty to Animals Act, and lately professor of hygiene in the R.A.M. College, has been appointed professor of public health in the University of Edinburgh.

UNIVERSITY OF CAMBRIDGE.—Upon the recommendation of the Special Board of Biology and with the sanction of the Financial Board, the Senate have agreed that the income from the benefaction of the late Mr. Grant and the corresponding benefaction of the trustees of the Rockefeller Foundation, should be made available for the general purposes of the Department of Pathology during the current academic year.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CLII.—THE TREATMENT OF IMPETIGO CONTAGIOSA.

Impetigo contagiosa has the distinction of being the commonest of all skin diseases, the preponderance being even more obvious in hospital than in general practice. Fortunately, in most cases its treatment presents no great difficulty.

Routine Method.

The principle upon which successful management of the condition is based consists in a frequent removal of the characteristic "stuck on" scabs by bathing, followed by the use of almost any weak antiseptic ointment. The most popular and most satisfactory application is an ointment of ammoniated mercury, 10 gr. to the ounce of vaseline. The routine of treatment has become so stereotyped that in many out-patient departments printed leaflets with the necessary directions are kept for distribution to the out-patients. The scabs are to be bathed off with warm water thrice daily and the ointment applied immediately. It is not advisable to cover the affected part (unless necessary to protect it against rubbing) with a dressing or bandage. Healing seems to take more quickly if the sores can be allowed to remain exposed to the air. Possibly this is because the streptococcus, the causal organism, grows best anaerobically. The essence of the treatment, then, lies in the frequent removal of the scabs by bathing, and this measure alone without any application of ointment would be sufficient to bring about healing in most cases, although perhaps more slowly than when assisted by the use of ointment. In any case the procedure indicated above is invariably successful in an ordinary attack such as is commonly seen on a child's face, the most typical situation of the disease. But in special circumstances and situations the method may be modified with advantage.

Modified Methods Suited to Special Conditions.

Pemphigus Neonatorum.—For example, in very young infants I am inclined to think that boric ointment is preferable to a mercurial ointment, even if very weak, because it is less likely to be irritating to the tender skin. In the newly born there sometimes occurs a condition known as pemphigus neonatorum. In this, as the name suggests, the tiny transitory vesicles of impetigo are replaced by large blisters. Unlike ordinary impetigo, although apparently caused by the identical streptococcus, this is a very dangerous disease and often ends fatally. Here boric baths are useful and it is sometimes possible to prepare and use an autogenous vaccine with good effect. But in bad cases this disease runs a very rapid course and the issue may be decided before the vaccine can be got ready.

Impetigo of the Scalp.—On the other hand, in impetigo of the scalp, the skin of which is less easily irritated than that of the glabrous regions, it is advisable to use a stronger ointment than usual—e.g., the ordinary unguentum hydrargyri ammoniati of the British Pharmacopœia, the strength of which is 25 gr. to the ounce. Moreover, it is to be remembered that impetigo of the scalp is very often secondary to pediculosis, and by using a fairly powerful mercurial ointment the primary disease may be cured at the same time.

Impetigo of the beard region is often awkward to deal with. On the one hand it is inclined to be aggravated by the daily shave, and any slight abrasion of the skin facilitates the spread of the eruption, while if the beard be allowed to grow the dried and encrusted discharge clings round the stubby hairs and makes it very difficult to keep the surface clean. Perhaps the best course is to compromise and to instruct the patient to shave on alternate days and to be careful to use a weak antiseptic solution (e.g., biniodide of mercury solution in a strength of 1 in 4000) both before and after shaving to lessen the chance of auto-inoculation. For the same reason it is wise not to attempt too close a shave, but the razor should always be very sharp as nothing irritates a tender skin so much as the pulling of a dull blade. Most men refuse to put ointment on their faces during the daytime, but they should be encouraged to bathe the face frequently with boric lotion to remove the quickly forming crusts, and they can at any rate employ ointment at night. Impetigo of the beard region is especially important because if neglected or unwisely handled it can easily become complicated by the advent of a secondary staphylococcic infection resulting in the production of furuncles, while simultaneously the whole surface of the skin becomes inflamed and erythematous. In short, we then have presented to us the clinical picture known as *sycosis*, a condition notoriously difficult to treat successfully. In cases of impetigo of the beard region the help of the pathologist and the early preparation of a vaccine may be extremely useful in preventing this untoward development.

Cracks and Fissures.—Another troublesome and sometimes obstinate development of impetigo is the formation of painful cracks or fissures, either at the corner of the mouth, in the vestibule or at the angle of the nose, or behind the ears. They sometimes seem to arise quite apart from any obvious impetiginous eruption, but bacteriological investigation shows that they are caused by the same type of streptococcus as is associated with frank impetigo and consequently can be considered as of like nature. Sometimes they heal up with simple ointments, but are prone to recur. I have known fissures resistant to the weak ammoniated mercury ointment which yield to it when 10 gr. of resorcin are added to each ounce. The stick of lunar caustic is often useful, especially if the fissure is bordered by rather exuberant granulations. This, as a rule, only happens when the crack is situated at the corner of the mouth and extends on to the mucous membrane. In more obstinate cases I have almost always found that one or two small doses (half a pastille) of X rays will promote sound healing and I have also had good results from ionisation with zinc.

Impetigo Secondary to Other Complaints.

A word of warning is necessary as to the treatment of impetigo when secondary to other complaints, such as eczema or scabies. When eczema is complicated by impetigo, which frequently happens in occupational eczema of the hands, the treatment of the impetigo, which is an integral part of the management of the case, must be conducted so as not to aggravate the primary disease. It is advisable in such cases to remove the scabs by soaking them off with olive oil or liquid paraffin rather than by bathing with water or watery solutions of antiseptics. In such cases, too, boric ointment is usually found to be more easily tolerated than a mercurial preparation.

When impetigo is grafted upon scabies, the primary disease is often effectually masked. It is important to be on the watch for this combination of eruptions as it is useless to treat the impetigo while neglecting the scabies. On the other hand, if the usual method of treating scabies be employed the impetigo will often disappear pari passu, and in any case will be favourably modified. Any widespread impetiginous eruption, in which the buttocks, groins, and axillæ are implicated, should put the practitioner on his guard, and any septic and pustular eruption on the hands is exceedingly likely to be secondary to scabies.

In babies and young children widespread impetigo may also be secondary to that common eruption which causes so many sleepless nights to children between the ages of 2 and 6 years, and to their parents, and which rejoices in so many names—e.g., gum-rash, strophilus, urticaria infantum, lichen urticatus,

&c. Here the secondary impetigo is very important because it forms part of a vicious circle. It aggravates the original disease, and consequently causes increased irritation and scratching, leading to more impetigo. The treatment of urticaria infantum itself, often a difficult problem, lies outside the scope of the present article; boric baths and boric ointment form the best method of attacking the impetigo, and when this has been subdued the little sufferers are often greatly relieved even as regards their urticaria.

H. Haldin-Davis, M.D. Oxon., F.R.C.S. Eng.,
Dermatologist to the Royal Free Hospital.

Special Articles.

ROYAL COMMISSION ON LUNACY AND MENTAL DISORDER.

(*Continued from p. 1085.*)

The Commission resumed its sittings at Old Palace Yard, Westminster, on Dec. 10th, Mr. H. P. Macmillan, K.C., presiding.

Supplementary Evidence of the Board of Control.

The witnesses attending were Sir Frederick Willis, Dr. Hubert Bond, and Mr. S. J. F. Macleod, all representing the Board of Control. The Chairman explained that these gentlemen had been asked to attend for the purpose of giving their views on certain general questions on which the Commission had been taking evidence, in supplement of the submissions which that Board made at a much earlier stage of the proceedings. He added that it might be necessary for the Commission to make some novel recommendations. The chief spokesman was Sir Frederick Willis. Asked specially about the incipient and the voluntary classes of case, Sir Frederick Willis said that the matters and views he was about to express had been very fully discussed by his colleagues on the Board, and they represented the views of the Board. It was desirable that patients suffering from mental illness should be divided into the following three classes: (1) voluntary, (2) non-volitional but passive, (3) resistant. This classification was based on an immense amount of experience in dealing with mental disorders. The Board thought the voluntary case might be received for treatment on his own written application (if under 18 years, on that of a parent or guardian), accompanied by one medical recommendation, into any mental hospital or nursing home, or into private care, subject to certain conditions.

Voluntary Cases.

The Chairman said that patients in the first of these classes realised the situation concerning themselves, but those in the second category were in a somewhat peculiar position as to the exercise of any restraint, for such restraint in their case would be illegal. It would really be treating a patient who had no volition without authority. Sir Frederick Willis replied that it was suggested that authority should be given by Act of Parliament. He said that the conditions suggested by the Board for these voluntary cases were: (*a*) notification of the admission of the case, with a copy of the medical recommendation, should be sent to the Board; (*b*) a medical report on the case should be sent to the Board within seven days of the admission, and thereafter at six-monthly periods; (*c*) should the Board have the right to inspect the place where the patient was being treated; (*d*) should it have the right to order the discharge of a patient from the voluntary class if their judgment warranted it; (*e*) if at any time the patient ceased to possess real volition and this defect continued, he should be, within a month, either dealt with under the provisions relating to the passive or resistant cases, or should be discharged; (*f*) that the patient should have the right to leave the treatment place at any time on giving in writing 72 hours' notice (the parent or guardian giving this notice in the case of a minor). Asked by the Chairman whether it was not sometimes difficult to draw the line in a voluntary patient between a mental and a physical case, the witness agreed, but said that the medical attendant would be able to say, and he could suggest a particular nursing home to the patient.

Sir David Drummond said that the need for notification of mental illness would militate largely against patients seeking early treatment. The witness replied that there would be no public intimation of what had occurred. As to the nursing homes, he thought the duty of saying what were physical and what were mental cases should be imposed on the medical man sending the cases. The essence of the Board's recommendations was that for these voluntary cases there should be no detention. Sir David Drummond asked if it was the view of the Board that all cases of neurasthenia should be notified.

Dr. Bond said he would rather not answer the question in that form. He would prefer to say that where the medical man considered a patient to have mental symptoms, or he thought the case a mental one, he should use these provisions, mainly with the object of protecting himself against the event of the case turning out differently. It was fear of the provisions of the present Lunacy Act which prevented and detracted from early treatment of mental conditions. This fear could be wiped away by the simple provisions now suggested. But how one was to lay down exactly to which cases this could be applied passed the wit of man. It was a question of diagnosis and medical opinion, and he would be sorry to see any attempt made to schedule exact symptoms, or to try strictly to demarcate them.

Sir David Drummond asked, in that case, how could the general practitioner be expected to do it?

Lord Russell said it was a question of degree. In the early stages of mental disorder it was difficult to know which cases required notification, but it was a long step from that doubtful stage to the stage in which it was necessary to institute legal proceedings.

The Chairman asked the witness, concerning clause (*c*) dealing with the right of the Board to inspect the place where the patient was being treated, whether, in the event of the Board being dissatisfied with the place, there should be power on the part of the Board to order the removal of the patient from it. Sir Frederick Willis replied in the affirmative. Asked whether it was proposed that the patient should be seen, he said this was not set down, but they would wish to be satisfied on the matter. The Board were anxious not to do anything which would interfere with this class of patient. The Chairman said it seemed difficult to know at what stage a voluntary patient would cease to be such, as the volition varied from day to day. Sir Frederick Willis agreed that there was no sharp dividing line.

Mr. Macleod instanced the case of a man admitted for voluntary treatment who, when asked at a later stage why he was there, replied that he did not need treatment, but was there because he was being persecuted. Such a case, at that stage, must either be discharged or certified.

Dr. Bond said there certainly were oscillatory cases in which the periods of insanity were evanescent, and one of the worst outrages which could be perpetrated on such a patient would be ordinary certification.

Passive Cases.

Dealing next with the non-volitional, passive case, the Chairman asked where the witness considered such should be received.

Sir Frederick Willis said this type of case might be received for treatment in any mental hospital or registered hospital, and if the institution or place had previously been approved by the Board for the reception of such cases, in any licensed house, general hospital, nursing home, or into private care, but subject to the following conditions: (*a*) that an application is made by a relative or friend, or by a public official for the reception of the case, accompanied by two medical recommendations; (*b*) that admission of the case is immediately notified to the Board, and copies of the two medical recommendations furnished to them; (*c*) that a medical report on the case is sent to the Board within seven days of admission; (*d*) that the institution is open to the inspection of the Board; (*e*) that the Board has the right to order the discharge of a patient from the "passive" class should they consider him unsuitable to remain on that footing; (*f*) that the person on whose application the patient was received for treatment should at any time have the right to remove the case on giving 24 hours' notice; (*g*) that if the patient recovers volition he should be allowed to leave on giving 72 hours' notice to the person in whose charge he is; (*h*) that if at any time the non-volitional but passive case becomes a resistant case, he must, within a month thereof, be dealt with under the provisions relating to the resistant type of case, or be discharged. He explained that the 72 hours' notice requirement was to allow time to communicate with the relatives of the patient in the event of his having developed dangerous tendencies, so that they would be enabled to take the further steps needed. He said the Board considered that the non-volitional but passive patient should only be received on the footing here stated for a period of six months in the first instance, but that there should be power to give a further six months if two independent medical practitioners recommended that, in the patient's interests, this was desirable, and if copies of the two medical reports were furnished to the Board. If after this year of treatment it was considered that the patient ought to be detained for further care and treatment, this should only be done after he had been fully certified. If the patient should recover volition and was willing to remain as a voluntary patient, he should be allowed to do so, subject to the conditions relating to voluntary patients.

The Resistant Case.

Sir Frederick Willis said the Board considered that the resistant case should only be detained after full certification, on a petition signed by a relative, friend, or public official, and an order signed by a judicial authority, subject to the following limitations: (*a*) that a case may be received on a provisional order signed by a relative, friend, or public official, and accompanied by one medical certificate. Under this, a patient may be detained for 14 days if, in the opinion of the medical officer of the institution or place, or—in the case of a patient under single care—the medical attendant, the case needs detention for that period. A copy of the provisional order and certificate should be sent to the Board on admission. If at the expiration of the 14 days the medical officer or medical attendant should be of opinion that the patient should be detained a further 14 days for observation and treatment, this may be done provided the doctor certifies, in writing, that the further detention is desirable. A copy of this certificate should be furnished to the Board. They recommend that detention of the resistant case beyond the 28 days should only be allowed under an order of a judicial authority on petition. These cases, say the Board, should only be received where suitable accommodation and expert medical treatment and nursing are available. They might go to any public mental hospital, registered hospital, or licensed house, and, if the institution or place had been previously approved by the Board for the reception of cases under a provisional order or certificate, to any general hospital, nursing home, or Poor-law institution, or under single care. They proceeded to say that cases fully certified should be received only in public mental hospitals, registered hospitals, or licensed houses, or in single care. And they might also be received in Poor-law institutions or in nursing homes which had previously been approved by the Board of Control. Sir Frederick Willis said the Board considered that the public responsibility for providing for all mental cases should rest with the visiting committee of the local authority, not with the guardians of the poor, and that if any Poor-law accommodation was used, it should be used in pursuance of a contract between the visiting committee and the guardians.

Evidence of the Ministry of Health.

The evidence at the short sitting on Dec. 11th was given by Mr. H. W. S. Francis, O.B.E. (Assistant Secretary of the Ministry of Health), whose work related especially to the Poor-law.

The Chairman explained that under the existing code of lunacy in this country there was an intimate relationship between that code and the Poor-law; and the Royal Commission had been considering the general question of that relationship and possible modifications of it. He asked the assistance of the witness as to any observations the Minister wished to make as to extricating, as far as possible, lunacy administration from Poor-law administration—i.e., whether the element of pauperisation associated with lunacy could be modified or altered. For instance, on the question of accommodation, a considerable number of patients were at present accommodated in Poor-law institutions, both certified and uncertified patients, and he understood these were directly under the charge of the guardians. The witness said this was so, and that some had become pauperised by the fact that a mental malady had overtaken them. The existing machinery provided for the use of Poor-law institutions as receiving houses for lunatics. He did not think there were many lunatics under Section 26 of the Act of 1890.

The Chairman asked where the population in the Poor-law institutions came from, and the witness replied that there were three elements: (1) those who came into the workhouses as receiving houses, perhaps on their way to an asylum, but who might be discharged without going to an asylum; (2) those who were already paupers and who became insane; (3) those who were discharged from the asylum and went back to the workhouse, where they were retained under the old provisions of the Act. Section 26 kept the lunatics in closer touch with county administration. If it were thought desirable to extricate the lunacy administration from its present association with the Poor-law, it might still be necessary to use Poor-law premises for mental patients, and by applying Section 26 the administration could be placed in the hands of the local authority. But in order that the Poor-law premises so used could become ad hoc branches of the lunacy system the Section seemed to need some development. There would have to be a transfer from Poor-law accommodation to asylum authority accommodation. No part of the expense due to this new course would fall ultimately on the guardians, though in the first case theirs would be the expenditure. In reply to a further question Mr. Francis said he did not see why there should be any substantial difficulty in regard to people already receiving Poor-law relief who then were visited by mental illness, as distinct from those who would be sent direct by asylum authorities. The evidence favoured the lunacy authority being responsible for all cases arising in its area, irrespective of the Poor-law. The medical officer of health and his staff offered a practical alternative to the present system, an alternative which was desirable.

The members proceeded to discuss the question of the forfeiture by a lunatic in a rate-aided institution of the old-age pension. Asked by Miss Symonds whether he considered the conditions and facilities now provided by the guardians were satisfactory, Mr. Francis said he thought that, generally, they reached a fair standard.

The Commission adjourned, no announcement as to future meetings being made.

PENSIONS FOR HOSPITAL OFFICERS AND NURSES.

A memorandum* setting out a draft scheme of pensions for hospital officers and nurses has been prepared by a conference composed of representatives of King Edward's Hospital Fund for London, the British Hospitals Association, the Incorporated Association of Hospital Officers, and the College of Nursing, Limited. Lord Stuart of Wortley, chairman of the Management Committee of King Edward's Hospital Fund, was the chairman of the conference, which included representatives from the provinces as well as from London.

Draft Scheme.

The draft scheme follows, generally speaking, the lines recommended in the report of a committee of the King's Fund, of which Mr. W. J. H. Whittall, F.I.A., was chairman. This committee reported that the provision of pensions for the staffs of voluntary hospitals, including nurses, was inadequate ; that this led to the age of retirement being unduly postponed ; and that the loss of all pension rights on migrating from one hospital to another was contrary to the interests both of the officers and of the hospitals. After commenting on the risks that would inevitably attach to any form of mutual pension fund, the committee recommended a scheme on the lines of the Federated Superannuation System for Universities, where policies are taken out with selected insurance companies. The present draft scheme is on the same basis, adapted to the circumstances of hospital and nursing service. The hospitals adopting the scheme would contribute 10 per cent. of salary and emoluments and the officers and nurses 5 per cent. The normal pension age would be 60 for officers and 55 for nurses. There would be a choice between three main types of policy : endowment assurance, giving a fixed rate of annuity at the retiring age or a certain sum at previous death ; deferred annuities with return of premiums on premature withdrawal or death ; and deferred annuities without return of premiums. The scheme, if adopted, would include the salaried staff, administrative, clerical, and dispensing, and also the whole nursing staff except probationers during their first year. Members migrating from one hospital to another, or from one branch of nursing service to another, would take their policies with them.

To nurses this freedom to migrate without loss of pension rights is specially important, since most of them begin their career in hospitals and then move into other branches of the profession. The scheme would cover the nurse's whole working life, and it would remove a hardship that now deters many suitable women from taking up nursing—namely, the impossibility of making adequate provision for old age. The promoters of the scheme urge the advantages of beginning at an early stage of training, provided that the hospital's contributions do not become the property of the nurse unless she remains in the profession at least five years. Special arrangements are suggested for enabling the policies to be maintained by nurses engaged in private nursing, though the details of this part of the scheme do not concern hospitals. The scheme would be administered by a central council representing the hospitals and the members ; and this council, through a special nurses committee, would deal with matters relating to nurses not in hospital service. The memorandum discusses the arguments for and against each of the above provisions, and is issued for the consideration of each individual hospital. The conference itself did not express any opinion other than general sympathy with the principle of a pension scheme, merely adding that, if the draft scheme proved acceptable to the hospitals, the advantages anticipated from it, both to the hospitals and to the officers and nurses, would be the more fully realised the larger the number of hospitals that joined.

VIENNA.

(From our own Correspondent.)

Late Reaction after Application of Radium.

At one of the recent meetings of the Vienna Medical Society Prof. Marschik demonstrated a man of 49, who had been treated by radium 18 months ago for ulceration of the soft palate. Histological examination of an excised portion had proved the presence of cancer, so radium was applied in 13 sittings, with a tube containing 50 mg. radium bromide. Each sitting lasted 30–50 minutes, the other parts of the mouth being apparently well protected. The ulceration slowly disappeared in January, 1925, but three months later it reappeared. Vigorous radium treatment was again instituted, but it was useless ; so the patient consented to an operation, performed in July, 1925, which resulted in a cure of the carcinomatous ulceration. But two months later the patient again came, because on the base of the tongue, just opposite to the place of the original ulcus, a slowly growing necrosis had been observed. This ulceration gradually sloughed away, and the mouth is now normal. Prof. Marschik noted that the larynx is specially liable to this late reaction. In his experience the susceptibility of the neoplastic cells to radium varies with their degree of differentiation—the less differentiated the more vulnerable—thus lymphosarcoma is easily affected, whilst epithelial carcinoma or other tumours with highly differentiated cells are much more resistant. He deprecated the use of the method of massive doses, which, in his opinion, should be abandoned. Diathermy was an excellent method for the treatment of late reactions to radium. In the ensuing discussion, Dr. Hofer said that he had seen a similar case of late necrosis in the ethmoid bone six years after the application of massive doses of radium. He said that Kumer and Freund were now very careful in the application of radium to the mouth ; Dr. Kumer applied a dental toothplate with a prolongation, in which the radium applicator is hidden, so that the surrounding parts are completely protected.

Sugar as a Preservative of Anatomical Specimens.

At the same meeting of the Vienna Medical Society Prof. Tandler showed a number of anatomical specimens in which the original colours and form were beautifully preserved. These specimens were 8–12 years old, but had not suffered any deterioration. The method is simple. It consists only in the immersion of the preparation or specimen in a concentrated solution of cane- (or beet-) sugar. The vessel is then closed hermetically. The superficial layers of the tissues become quite translucent. The specimens can be exposed to the heat of an epidiascope without suffering damage. Sections through the brain, the kidney, the intestinal canal and the sexual organs were demonstrated. It may be added that the ancients in Western Asia, in Syria, and Mesopotamia used honey for embalming purposes. One of the old historians relates of a king who carried the dead body of his favourite wife with his chariot in all his wars, the body being preserved by means of honey.

Prize for Essay on Cancer.

The Austrian Society for investigating and fighting cancer has again resolved to offer for the year 1925 a prize of about £50 to the author of a paper which is held to promote our knowledge of the cancer problem in a fundamental way. Competition is restricted to Austrian investigators, and the prize will be awarded only if the paper is actually an advance on the present state of knowledge. Alternatively, the sum will be used in any way as seems desirable to the chairman of the society. All scholars and scientists of Austria are invited to compete, whether they be medical men or not; the paper must have been published between Jan. 1st, 1925, and Jan. 31st, 1926. The judges consist of the committee of the society.

Clinical and Experimental Studies on Serous Cavities.

Dr. Schönbauer, of the Eiselsberg Clinic, recently read before the Gesellschaft der Aerzte in Vienna a paper in which he dealt chiefly with the serous membranes of the different body cavities. He has found that a diseased or injured serous membrane has a much diminished power of absorption, which is lessened still further by the injection of concentrated solutions into the cavity. This lessened absorption does not last long. The observation holds good for the peritoneum, the pleural cavity, or the meninges; but hypertonic solutions (10 per cent. NaCl, or sugar, or urotropine) are not long effective, and experiments have shown that, for instance, in diffuse perforation peritonitis, the liquid cannot be injected except during operation. In his search for a strong bactericidal solution he found that pepsin hydrochlorid answers the purpose best. In 103 cases of peritonitis after perforation, treated with this solution, the mortality was 11·7 per cent., which is only about one-third of the previous mortality. The absorption of poison into the system is markedly retarded by injecting pepsin hydrochlorate into the peritoneal cavity. In paralytic ileus after operation or perforation animal experiments have proved that intoxication is prevented by using a strong antitryptic serum; two successful results have followed its use in human cases. A second series of experiments dealt with the pleural cavity. Here, too, Dr. Schönbauer could prove that absorption is lessened by inflammation, and that it can be lowered further by injection of hypertonic solutions. Therefore he advises in acute cases of empyema the use of aspiration of the greater part of the pathological material and the injection of a hypertonic solution before the pyothorax is completely emptied. Similar experiments were conducted on a number of animals with regard to the conditions of the meningeal membranes. Dr. Schönbauer discussed the details of these interesting experiments, which have a bearing upon otologic operations; he showed that in traumatic meningitis lumbar puncture may spread the infection of the meninges, but, on the other hand, by injecting hypertonic solutions of 40 per cent. urotropine into the spinal canal an extension of the infection was effectively checked. The experiments will be controlled shortly on patients in the otologic clinics.

Decrease of Syphilis in Vienna.

Investigations conducted on a large scale in this country have shown, as Prof. Finger recently said in the Austrian Board of Health, that 12–14 per cent. of the entire population were at one time infected with syphilis or gonorrhœa. Since 1922, however, records kept in hospitals and dispensaries show that a rapid decrease of primary syphilitic infection has taken place, at least in Vienna. Systematic instruction and teaching of the public, promoted by the Society for the Prevention of Venereal Diseases, together with excellent facilities for early and intensive treatment of all infected persons, is considered to have brought about this change, coupled with modern methods of diagnosis and prophylaxis and treatment. The early recognition of a primary sore enables the timely and adequate treatment of the patient and thus stops many potent sources of spreading infection. In the country, however, this rapid decrease is not so clearly manifest although it is also evident. It happens now that in several provincial hospitals the number of fresh cases of syphilis exceeds in one month those seen in the Vienna clinic at the same time. Especially the younger people are now oftener affected than formerly, most likely due to the radical change of economics and morals which has taken place in the last ten years. But with the comparative disappearance of primary sores the secondary lesions become more rare—as shown by the reports from competent factors—and we are entitled to the hope that in due time the dreaded disease may be really wiped out. The public is now impressed with the statement that syphilis *can* be cured if treatment is commenced early enough. The more this is hammered into the minds of the population the earlier a radical improvement of public health is to be expected.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Increasing University Fees.

FROM the first day of 1926 fees at the University of Paris will be raised by 50 per cent., the regular trimonthly levy of 40frs. for the undergraduate courses becoming 60frs., and other fees being affected in similar proportion. French students belonging to families including three or more children are entitled to free instruction and generous remission of the ordinary charges. This provision is extended to families which have lost children in recent military or civil service.

Annual Meeting of the Academy of Medicine.

At the annual public meeting of the Académie de Médecine on Dec. 8th the commemorative eulogy was delivered by Prof. Achard on Jacques Raphael Lépine, of Lyons, who died in 1919. Lépine, who looked at medicine from the physiologist's viewpoint, was a pupil and friend of Cruveilhier, Claude Bernard, Vulpian, Charcot, Virchow, Cohnheim, and Pasteur. Among his contributions to medicine were the discovery of centres governing the heart-beat, vasomotor reactions, blood pressure, and movements of muscles in the hand and face; he made a special study of the perivascular channels of the brain, and the causation of pseudo-bulbar paralysis, and the action of caffeine, digitalin, strophanthin, atropine, and sodium benzoate. Lépine helped to establish the unitary character of tuberculous lesions, and his labours on diabetes are familiar. A number of prizes were awarded at this meeting. The Prince of Monaco prize of 100,000frs. went to Laguesse and Hédon for their discovery of the internal secretion of the pancreas. Debré received 4800frs. for his work on convalescent serums, especially in measles. Levaditi was awarded 12,000frs., Maygrier 6000, Marquézy 3000, and Guillaume 3000frs.

Clandestine Sale of Narcotics.

Traffic in cocaine, heroin, and other narcotics continues to be very considerable at Paris. Montmartre is the largest centre. From houses and "merchants" in this part of Paris representatives are distributed rather widely over the city. Four dealers have just been arrested on the charge of homicide by imprudence, death of a young Russian student through heroin poisoning having led to investigation and discovery. Charges are also being filed against several of the clients. The only penalty against the narcotic traffic at present is the occasional infliction of imprisonment for a period not materially embarrassing to the offender.

Milk and Child Welfare.

Since Dec. 1st the Paris milk-supply has become very irregular and insufficient. A number of proposals have been presented to the municipal council, advocating limitation of the sales of milk in cafés and restaurants, use of milk cards for children and the sick and aged, and distribution of milk among the different arrondissements on a population basis. These projects will be considered at once. The Pierre Budin Foundation, of which Prof. Comby is president, provides regular free instruction in prenatal and infant care for students, physicians, nurses, young mothers, and all who may be interested in the subject. It also supplies from its station in the rue Falguière annually some 15,000 litres of milk, sterilised by the Soxhlet-Budin method.

On the motion of the Ministries of Finance, Labour, and the Interior, a census of the French population has been fixed for March 7th, 1926.

A regional anti-cancer centre has just been installed and opened at Rheims. The centre will promote active educational propaganda on the prevention and treatment of cancer.

The new legislation defining the rights of occupants and proprietors of houses cannot come into force until April 1st, 1926. After that date occupants must meet the advanced rents or vacate.

Prof. Widal's clinic at the Hôpital Cochin opened on Dec. 15th. Clinical lectures are given daily at 9 A.M.; lectures in the amphitheatre every Tuesday at 11 A.M.

At the Sorbonne, Dr. Sicard de Plauzolles is giving free public instruction on syphilis, gonorrhœa, tuberculosis, and other social diseases; on Tuesdays in the Milne-Edwards amphitheatre, and on Saturdays in the amphitheatre Edgar Quinet. The time is 5.30 P.M. These conferences are under the auspices of the National Office of Social Hygiene.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

The Doctor and the Changing Order.

THE President of the Rockefeller Foundation, Dr. George E. Vincent, spoke on the above theme recently to the New York Academy of Medicine. A chiefly urban, minutely specialised, and highly interdependent industrial, commercial, and social system confronts the modern doctor, he said, with new problems. His former individualistic neighbours, the merchant, banker, manufacturer, even lawyer and teacher, have been drawn into organisations and have largely lost their independence as self-sufficing units. Must the doctor, who can now master only a part of the vast total of medical knowledge and skill, follow in their footsteps? It is recognised that effective medical care demands insistently an individual relationship between doctor and patient. There is thus created a conflict between the social need for team-work on the one hand and the demand for human insight and sympathy on the other. In seeking a solution Dr. Vincent reviewed the voluntary health insurance schemes of Denmark and Norway and the compulsory insurance in Germany and Great Britain, concluding that "the medical care is probably on the whole inadequate and certainly unorganised." Only in university clinics, in well-developed hospitals, dispensaries, and pay clinics, in true group practice, and in health centres is there to be found genuinely organised medicine. But these organisations, too, are subject to criticism. Are they not mechanising medicine, eliminating the personal relation? Perhaps, replies Dr. Vincent, but it is clear in any case that the old order is changing. It looks as if society means to insist upon a more efficient organisation of medical service for all groups of people, upon distribution of the costs of sickness over large numbers of families and individuals, and upon making prevention of disease a controlling purpose.

Alcoholism in 1925.

The very impartial report on prohibition recently issued by the Federal Council of Churches was in itself so inconclusive as to the final outcome of the present legislation that the Council has found it necessary to issue a special announcement of its unchanged advocacy of prohibition and law enforcement. The figures on alcoholism for the first nine months of the present year issued by the Metropolitan Life Insurance Company show that the death-rate from alcoholism is 2·8 per 100,000, compared with 3·2 per 100,000 for the corresponding period of 1924. The deaths from cirrhosis of the liver have, however, increased from 673 to 823, a rate of 6·3 for the first nine months of last year and 6·6 for the same period in 1925. Poisonings by wood or denatured alcohol have also increased. Since the beginning of 1922 alcoholism (excluding cases of poisoning from wood or denatured alcohol) has accounted for the deaths of 1528 industrial policy-holders in this company. Other items from this report show that the death-rate from typhoid fever continues to decline among the white population but has actually increased among the coloured population, standing at the appallingly high rate of 11·4 per 100,000 in the latter case. There is a continued decline of tuberculosis deaths in both white and coloured. The deaths from automobile accidents continue to increase.

Periodic Physical Examination.

The conference of secretaries of State medical societies to study and promote a scheme of periodic medical examinations was a lively occasion. At the present time while the American Medical Association, the National Health Council, and the Gorgas Memorial are all promoting such examinations, the work is largely done by business organisations for gain. One such corporation speaks of employing upward of 8000 medical examiners, others are no more than the one-room commercial laboratory. The conference deprecated the need for any middleman between physician and patient, and set its face strictly against the commercialisation of medical practice.

Public Health Services.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

THE following are some of the health statistics for 1924 of a group, comprising three counties, three county boroughs, and three cities:—

Name of district.	Estimated mid-year population (R.-G.).	Birth-rate.	Death-rates per 1000 of the population.				Death-rates per 1000 births.		
			All causes.	Tuberculosis.	Cancer.	Resp. diseases with influenza.	Neonatal mortality.	Infant mortality.	Maternal mort. from childbirth.
Kent	1,107,800	16·6	11·1	0·95	1·38	1·9	26	53	3·3
Staffordshire .	718,400	21·6	11·4	0·90	0·89	2·8	36	79	2·7
Huntingdonshire	55,700	17·2	12·5	0·82	1·54	2·0	37	60	4·2
Birkenhead C.B.	154,100	21·1	11·9	1·21	1·16	2·9	36	92	2·8
South Shields C.B.	126,600	24·3	14·5	1·62	0·98	3·8	42	102	5·2
Bournemouth C.B. ..	84,450	13·2	13·8	1·10	1·80	2·3	26	45	0·9
Norwich C. ..	123,900	17·5	11·6	1·22	1·51	2·0	26	62	1·9
Carlisle C. ..	54,910	20·3	13·8	1·25	1·31	2·5	30	95	2·7
Gloucester C. .	53,090	19·6	12·6	1·32	1·26	2·3	34	83	3·8

C.B. = County borough. C. = City.

Kent.

Dr. Alfred Greenwood reports that the death-rate from cancer remained at the same high level as in the preceding year. Some very high rates were recorded in the various districts; thus, Deal borough had a rate of 2·13 for 1924, New Romney a rate of 2·03, and among the rural districts Elham had a rate of 2·11 and Tenterden a rate of 2·20. Dr. Greenwood assisted the publicity work by giving popular lectures on this subject to the lay public in various centres of population in the county. These lectures, illustrated by lantern slides and framed in simple language, proved to be a great attraction. The arrangements were made by the local medical officers of health in each case. Very large audiences were addressed and the modest cost was borne by the local council.

Successful administration of the county tuberculosis scheme continues, but, says Dr. Greenwood, " still further benefits may accrue when it is possible to ally with our work in this direction greater expedition in the provision of houses, with consequent improvement in home conditions and less overcrowding. Further accommodation for patients suffering from pulmonary tuberculosis in its early stages is now being arranged at the county sanatorium at Lenham, owing to the training section at that institution being discontinued by the Ministry of Health. Forty additional beds will become available shortly. An outbreak of paratyphoid fever in the borough of Dover was traced, after a considerable amount of difficulty owing to the complicated methods of milk distribution, to a " carrier " working on a farm outside the borough. The sanitary defects found on the farm contributed to the spread of infection. The " carrier " was isolated in hospital for two months and left at his own request, giving an undertaking that he would not in future follow an occupation which involved the handling of any foodstuffs used by the public. The work of the county bacteriological and pathological laboratories at Maidstone continues to elicit the cordial appreciation of the medical profession throughout Kent, and the number of examinations again shows an increase.

Continued efforts are being made to provide an efficient midwifery service throughout the county either by making grants to assist in the formation of district nursing associations, or by placing subsidised midwives in districts where a livelihood cannot be obtained from midwifery alone. Some 18 districts are now served by subsidised midwives. A very successful post-certificate course for midwives, comprising lectures and demonstrations, was held at Gillingham from Oct. 6th to 10th, and was attended by 125 practising midwives and 24 health visitors.

Staffordshire.

Dr. W. D. Carruthers reports that there are now only 47 untrained midwives and 225 trained midwives as compared with 438 untrained midwives and 18 trained at the time of the passing of the Midwives Act. The provision of an efficient service has been one of the chief concerns of the public health committee for a considerable period. In the more populous districts, if the midwifery service is inadequate, either a midwife is trained at the expense of the county council on the condition that she practises in a selected area for three years, or a trained midwife is established with a guaranteed income of £120 a year on condition that she does not select her cases. The latter method is the one usually adopted, and experience has shown that such midwives do not require a subsidy for as long as three years. There are 62 local nursing associations affiliated to the County Nursing Association, and eight non-affiliated which undertake midwifery. The smaller nursing associations in the county employ nurse-midwives, who are generally called village nurses. In addition to holding the certificate of the C.M.B., these village nurses have received a six months' training in general sick nursing at the Tipton Training Home. At the October meeting of the health committee a special scheme of post-certificate training was adopted for the practising midwives under which 70 practising midwives annually will attend a refresher course of a fortnight's duration at the Tipton Training Home. Arrangements will also be made to give the pupil midwives one month's practical training in health visiting. Antenatal work is also to be developed at all centres as far as possible.

An examination of the returns of the district medical officers of health has shown that in 9 out of 48 sanitary districts there were more deaths from pulmonary tuberculosis than notifications. Work with regard to the prevention of rivers' pollution makes progress and many of the districts in the county have bio-aeration schemes in hand.

Huntingdonshire.

Dr. C. B. Moss-Blundell says a great deal more should be done to improve the condition of the children. The education committee have provided for the treatment of eye defects, but tonsils and adenoids are neglected. Dental treatment is a crying need. Verminous heads are quite unpardonable, and Dr. Moss-Blundell thinks it would be a " Heaven-sent blessing if fashion dictated the Eton-crop for all time for all school-children." For venereal diseases an additional centre is needed in the north of the county, as also for tuberculosis ; and a new clinic for school-children should be established at Fletton. The problem of mental deficiency becomes more acute as there is no suitable institution available. Dr. Moss-Blundell is sorry that the Fowlmore aerodrome was not acquired for this purpose, and suggests that Huntingdon should combine with one or more other counties to acquire a suitable place.

Birkenhead.

Dr. D. Morley Mathieson reports that the regular bacteriological examinations made at the Alwen water-supply showed that the water was of remarkable purity and remained so throughout the year. The revision of the tuberculosis register shows that at the end of 1924 it included 1600 cases of tuberculosis of all types. This is rather more than five times the notifications for 1924, which number 294. Only 62·5 of the cases were notified to the department three months or more before death, but this is a slight improvement on the three preceding years. Owing to the fact that more beds are now available for adults at the Cheshire Joint Sanatorium at Burntwood, it is possible to admit more children suffering from surgical tuberculosis to the Thingwall Sanatorium. These children do very well at Thingwall, and the light treatment has been adopted with much success. Twelve beds are also reserved at Leasowe Hospital for surgical tuberculosis.

A scheme has been approved by the education committee for dealing with crippled children, comprising an orthopædic clinic, hospital accommodation for non-tuberculous cases, the provision of splints, &c., and the services of an orthopædic surgeon, an orthopædic nurse, and a masseuse. The clinic will be held on Saturday mornings at the central premises occupied by the Birkenhead and Wirral Invalid Children's Association, which association is already subsidised by the corporation and employs a masseuse. Hospital accommodation will be provided at Leasowe on the " patient-day " basis and £150 is included in the estimates for the first year. Mr. Hartley Martin, the senior surgeon of Leasowe Hospital, is recommended as the orthopædic surgeon, and for the first year it is estimated that one attendance by him per month at the clinic will be sufficient. On the intermediate days the orthopædic nurse will be in attendance. The added cost of the scheme for the first year is estimated at £270, half of which will be received back in the form of a grant to the education committee. Dr. Mathieson draws attention to the limited scale of the dental inspection and treatment provided for the school-children. Only one group is dealt with —namely, children born in the years 1914, 1915, and 1916. The result to these is excellent, but the other children in the elementary school remain outside the scope.

South Shields.

Dr. W. Nicoll states that the devastating effects of the influenza epidemic, which prevailed in the earlier part of the year, were severely felt on Tyneside. Excluding the memorable epidemic of 1918–19, South Shields was more severely affected during 1924 than in any year of the last 30. Nearly a third of all the notified cases of primary pneumonia died, and about half of the cases of influenzal pneumonia. The influenza epidemic was followed by cases of encephalitis lethargica ; nine cases were notified, eight of which died.

As a sequel to the visit of a Medical Inspector of the Board of Education, the question of the school dental service was raised anew and a full-time dentist appointed in place of two part-time dentists. A second full-time dentist will be needed quite soon. Another need of South Shields is increased and improved hospital accommodation for infectious cases. As a makeshift, huts have been erected in the grounds of the hospital. There is no observation block for dealing with doubtful cases and there are no segregation cubicles at the hospital. The death-rate from tuberculosis, which has been very high for some time, showed a drop during 1924. Among the 205 deaths from tuberculosis there were ten of Arab seamen, and Dr. Nicoll points out that they suffer more than the rest of the population. Arabs only constitute about 0·4 per cent. of the total inhabitants. A letter has been addressed to all the midwives, pointing out that when medical aid is required they should send for the medical practitioner desired by the patient. An antenatal clinic, under the charge of Dr. Susan Jamieson, was opened in June.

Bournemouth.

Dr. A. D. Edwards points out that the infant mortality was the lowest ever recorded in Bournemouth, and expresses his appreciation of the excellent work done by the Bournemouth Voluntary Association in all the centres. A fifth centre had to be opened towards the end of the year. The public analyst, Mr. R. A. Cripps, discusses the question of shredded suet. The rice flour in the samples submitted varied from 0 to 23 per cent. The object of the addition is to prevent the granules of fat becoming massed together. For this purpose from 10 to 15 per cent. (according to the hardness of the suet) of rice flour is ample. Consequently, all samples containing more than 15 per cent. must be regarded as adulterated. As the result of the action taken during 1922 and 1923 the use of preservatives is decreasing. Eleven out of 29 sausages contained boron, but only in one case in excess of 0·25 per cent. Five samples of fish paste and 22 of sponge cake were all free from boron. Ten samples of margarine contained boric acid in excess of 0·2 per cent., while 10 out of 11 samples of butter were also boricised but in only three in excess of 0·2 per cent. Nine samples of lemon squash, lime-juice, &c., all contained either sulphurous or salicylic acid. Mr. Cripps expresses his surprise that boric acid, "which has been used for many years under official sanction in preserved cream, butter, &c., and salicylic acid, which has been similarly favoured in various beverages, are now to be forbidden." He is doubtful as to whether the substitution of sulphites for boric acid will be advantageous, especially as the consumer will be liable to take a medicinal dose with less than ½ lb. of sausages.

Norwich.

Dr. H. Cooper Pattin reports that provision has now been made for the dental treatment of nursing and expectant mothers and is already proving beneficial. There is need for increased ward accommodation at the maternity home. The development of the Stanninghall colony progresses slowly. The Ministry does not quite approve of this being used for all types of tuberculosis, but appears to have a preference for a combined eastern counties hospital for surgical tuberculosis. The school dental officers find defects in 65 per cent. of all the children examined. With the appointment of a second dental officer more children now receive treatment, and it is hoped that arrears will ultimately be overtaken. New houses do not meet the needs of the natural increase of the population. The housing scarcity, therefore, becomes aggravated, and the difficulty is rendered greater by the worn-out condition of much of the house property in the city.

Carlisle.

Dr. Joseph Beard reports six notifications of encephalitis lethargica. One was a non-resident who died in the infirmary. Of the remainder three made complete recoveries, one recovered except for a slight dilatation of the pupil, and the fifth made an apparent recovery, which was followed a month later by difficulty in swallowing and other grave symptoms leading to a fatal end. Dr. A. C. B. McMurtrie reports that syphilis is declining and looks forward with confidence to the time when syphilis in Cumberland will be almost a thing of the past. Gonorrhœa, on the other hand, he thinks is increasing. His opinion is illustrated by charts showing the number of new cases treated at the Cumberland Infirmary since 1920.

Gloucester.

Dr. Ronald B. Berry draws attention to the inadequate and extremely inconvenient accommodation provided for the health and school medical departments. During the year there was an outbreak of enteric fever of a mild type among children. Investigations showed that the children had probably become infected by drinking from a brook contaminated by sewage from the second county asylum. The outbreak led to an examination of the city water-supply, some of which was found to be unsatisfactory. The undesirable water came from the Robinswood Hill supply, and, after a survey of the gathering grounds, it was decided to dispense with the water from this source. The report on the dental scheme for expectant and nursing mothers shows that this work is growing in popularity, and that prejudice is disappearing. Treatment consists mostly in extractions, but occasionally the "Ivory Cross," a philanthropic association subscribed to by dentists, helps to provide artificial dentures. The present state of the housing problem makes all branches of the work of the health department exceedingly difficult. Dr. Berry thinks much more could be done in the way of open-air classes at the elementary schools. The school dental officer, Mr. L. Machin, reports that the dental scheme has received a very decided check from the system of charges instituted towards the end of the year. The majority of parents refuse treatment rather than pay.

SCHOOL MEDICAL SERVICE.

THE following table summarises the statistics for Manchester, Birmingham, and Northampton :—

Name of district.	No. on roll.	Average elem. school attendance.	No. of routine children examined.	No. of special examinations and re-inspections.	Percentage of children found on routine examination requiring treatment.†
Manchester . .	—*	—*	29,920	140,344	27·71
Birmingham .	140,738	124,019	42,736	67,354	26·99
Northampton	26,723	—*	6,479	2,183	24·8

* Not given. † Excluding dental defects and uncleanliness.

Manchester.

In addition to the routine work, Dr. A. Brown Ritchie and his staff examined between 6000 and 7000 children prior to their visit to Wembley exhibition —no light task when it is seen that the routine work has been fully and efficiently carried out. The increasing interest and knowledge of the medical work amongst the teachers are shown by the early recognition and notification of many cases of infectious diseases, but cases of defective vision and hearing still escape the teacher's notice. Extensive treatment is carried out by the staff at the various treatment centres—even minor orthopædic cases being treated.

Many special classes, residential, and day schools exist for the abnormal children, but Dr. Brown Ritchie states there is still a shortage of accommodation for blind, deaf, and mentally defective children. Dr. H. Herd reports on the after-results of encephalitis lethargica in 57 children in whom he found 20 cases of Parkinsonian syndrome (14 serious). Dr. J. G.

Woolham carries on from last year his investigation into the fitness of school-boys. He finds that, apart from the psychological development of the boy, his fitness depends on the anatomical proportionality between the parts or "static" state and on the physiological adjustability or "dynamic" capacity. While the "static" state can be measured, actual working experiments must be made to estimate the "dynamic" capacity which, he suggests, depends on the fitness of the vegetative systems and neuromuscular systems. Using his tests, he found that the distribution of 81 boys into seven grades closely corresponded with the numbers which would fall in each division drawn under a normal probability curve. Under similar tests, a "random sample" of boys in poor health were graded and showed close positive association with that found on purely clinical examination. Fully detailed tables are given in this praiseworthy and painstaking piece of research. Dr. G. W. Matthews has found that boys in abnormal standard for their ages have abnormal blood pressure.

Birmingham.

Dr. G. A. Auden's report makes interesting reading. Much work has been undertaken and the conclusions drawn are sound. Drs. B. and J. Alexander report on the remarkable preponderance of short-sightedness amongst Hebrews in comparison with children in non-Jewish schools—30 per cent. of the Jewish children were myopic whereas the non-Jewish children culled from a similar environ showed only 12½ per cent. of defective vision and these were hypermetropic. Commenting on the orthopædic and remedial exercise clinic, Dr. Auden says: "It has been stated on unimpeachable authority that from 80 to 85 per cent. of the crippling now extant can be prevented or cured by appropriate and skilled treatment." The marked reduction in the incidence of ringworn has continued and the X ray treatment has caused a great diminution in the loss of school attendance. It is estimated that the saving on the 366 cases by X ray treatment is equivalent to 139·4 educational years.

Northampton.

Dr. Charles Paget, M.O.H. and school medical officer, states that, owing to illness of his staff, the number of routine inspections is not complete. He reports favourably on the good nutrition of the children, which is being well maintained.

He has a shrewd paragraph on the subject of squint. We are all familiar with the parent who thinks his child will grow out of it and with his consternation when testing of the squinting eye reveals the fact that its vision is already seriously impaired. As Dr. Paget states, glasses should be adopted early and worn constantly and the disused eye regularly exercised by the use of a shade over the good eye. There are apparently no special schools, though there are 151 mentally defective children and many suitable for physically defective and open-air schools. Such provision is undoubtedly difficult in scattered rural areas, but the absence of facilities is hard on the individual children.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 5TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 115 (last week 105); scarlet fever, 1963; diphtheria, 1005; enteric fever, 57; pneumonia, 1776 (previous weeks 1531, 1186, and 889); puerperal fever, 51; cerebro-spinal fever, 5; acute poliomyelitis, 4; encephalitis lethargica, 51; dysentery, 6; ophthalmia neonatorum, 109. There were no cases of cholera, plague, or typhus fever notified during the week.

Deaths.—In the aggregate of great towns, including London, there was 1 death from enteric fever (London), 58 from measles, 11 from scarlet fever, 32 from whooping-cough, 59 from diphtheria, and 100 (previous weeks 73, 61, and 44) from influenza. In London itself there were 26 deaths from measles, 24 from diphtheria, and 22 from influenza.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lts. (D.): O. J. Barrable to *Victory*, for R.N. Barracks, Portsmouth, temp. and to *Impregnable;* and L. B. Osborne to *Vivid* for R.N. Barracks, Devonport, temp.

ROYAL ARMY MEDICAL CORPS.

Capt. E. C. Lang to be Maj.

Capt. R. W. D. Hewson to be temp. Capt. and temporarily relinquishes the rank of Capt.

A. L. Moorby to be temp. Lt.

ARMY DENTAL CORPS.

Capt. R. H. Mills retires on account of ill-health, receiving a gratuity.

TERRITORIAL ARMY.

Maj. F. W. B. Young, T.D., to be Lt.-Col. and to command the 164th (West Lancs) Field Ambulance.

Lt. J. H. Iles to be Capt.

Lt. F. R. Sandford (from Supernumerary for service with the Univ. of Lond. Contgt. O.T.C.) to be Lt.

D. C. Vaughan to be Lt.

DEATHS IN THE SERVICES.

Sir HENRY FREDERICK NORBURY, K.C.B., Director-General, R.N. retd., honorary surgeon to the late King Edward and to King George, died at Eltham on Dec. 10th, at the age of 86. An old Bart.'s man, he qualified with the M.R.C.S. and L.S.A. in 1860, in which year he joined the Royal Navy. Ten years later he graduated M.D. at the University of Malta and was appointed staff surgeon in 1872. While serving in the *Active* at the Cape and West African stations he was landed in medical charge of the Naval Brigade during the Kaffir War of 1877–78. He also served in the Transkei as senior medical officer of six different columns of troops, was present in numerous skirmishes, in the action at the Quorra River, and at the battle of Quintana (mentioned in despatches and recommended for promotion). During the Zulu War of 1879 he was in medical charge of the *Active's* Naval Brigade and was P.M.O. of Colonel Bearson's column, being present at the battle of Inyezane. Later he was P.M.O. with General Crealock's column (mentioned in despatches, medal with three clasps, promoted to Fleet Surgeon and was made a C.B.). For three years he served in charge of the Naval Hospital at the Cape and during that period was awarded the Blane Gold Medal on passing for staff surgeon. Subsequently he joined the Naval Hospital at Stonehouse, Portsmouth, and the *Impregnable* training ship for boys at Devonport, where he remained till 1887, when he was appointed Deputy Inspector-General of Hospitals and Fleets, when he was attached to the Royal Naval Hospital at Plymouth previous to being transferred to the Medical Director-General's Department as an assistant to Sir James Dick, the then Director-General. In 1895 he was appointed senior medical officer at Plymouth Hospital with the rank of Inspector-General. In 1897 he was promoted to K.C.B., and in the following year succeeded Sir James Dick as Director-General of the Naval Medical Service, retiring from that position in 1904. Sir Henry Frederick Norbury, who was the author of "The Naval Brigade in South Africa," was made an honorary Fellow of the Royal College of Surgeons of England in 1900. He was also a Knight of Grace of the Order of St. John and was a member of several learned societies. He was awarded a special pension for good service on the active list. Sir Henry Norbury married in 1868 Mina Legge, daughter of Mr. E. G. Wade-Brown, of Burton Bradstock, Dorset, by whom he had three sons and five daughters. One of the sons, Mr. L. E. C. Norbury, is a well-known surgeon, and three of the daughters are married to medical men.

Surg. Rear-Admiral C. M. Beadnell has been appointed honorary physician to the King, vice the late Surg.-Gen. C. Pearson; and Surg. Rear-Admiral A. Maclean honorary surgeon to the King, vice the late Surg.-Gen. H. J. M. Todd.

STAFFORDSHIRE INFIRMARY.—Last week Sir John Bland-Sutton opened a new operating theatre, which has cost £5000, at the Staffordshire General Infirmary, Stafford. The theatre was designed by Sir Aston Webb.

EXTENSION OF RUGBY HOSPITAL.—The Hospital of St. Cross at Rugby, which at present contains 100 beds, has become so inadequate to the needs of the district that a committee which has been considering the position recommends an immediate extension to 115 beds, with a further addition, a little later, which will increase the total capacity to 150 beds.

PROPHYLACTIC INOCULATION AGAINST "COLDS" AND INFLUENZA.

To the Editor of The Lancet.

Sir,—There are some difficulties and even dangers in carrying out Dr. A. I. Simey's suggestions to inoculate schools wholesale. These are touched upon but not emphasised in his article in The Lancet of Nov. 21st: (1) There is the variation in immunity of individuals; (2) there is the method of administering the vaccine; (3) there is the composition and method of preparation of the vaccine.

(1) Variation in immunity is recognised. Some people are frequently "catching" colds or influenza, some rarely have either colds or influenza. Some have a chronic post-nasal catarrh, which in time infects the larynx and bronchial tubes. Some have no apparent catarrh but the organisms lie latent, ready to develop in virulence and number if the individual gets chilled or overtired. When we have recognised this variation in immunity we might express it thus—individuals may have an immunity ranging from 0 to 100; let us divide them into five groups, A has no immunity, B's immunity may be placed at 25, C's at 50, D's at 75, and E's at 100 We can only roughly guess in any individual case whether he should be placed in group A, B, C, D, or E. If, then, you proceed to inoculate him with one of the prophylactic anti-catarrh and anti-influenza vaccines, and if you give it in two doses as suggested by Dr. G. T. Western (The Lancet, Nov. 28th), presumably you give him ½ c.cm. for the first dose. What will happen? If he is in C, D, or E group he will get slight redness at the place of inoculation and possibly slight catarrh next morning and then will be all the better for it; but if he is in A or B group or between B and C he may get a heavy cold with or without a rise of temperature, which lasts on some time and does not produce an immunity; if anything, the immunity is lowered; and, indeed, in some cases bronchitis or pneumonia may follow.

(2) This brings us to the question of the *method* of administering the vaccine. The ideal to aim at is to produce a slight response in the individual by giving a dose which he can easily overcome. Clinically this means that if you are uncertain as to the immunity of the individual you must begin with a dose small enough to do no harm and watch its effect; the individual must not risk getting tired during the 24 hours following a dose, for the process is one of interaction between the dose of vaccine and the patient's powers of response. Therefore it is safest to begin with a dose of 0·1 c.cm. in adults and perhaps 0·05 c.cm. in children under 12. By observing what has happened during the 48 hours following the dose you are in a position to judge what dose to give next; if there has been a slight reaction following the dose you repeat it again at the end of three or four days or when the patient has got over it. Probably after repeating it a second time there will be no reaction and you can proceed to a higher dose. But in some cases where the immunity is very low it requires a great deal of patience before proceeding to higher doses. If, then, you make it your principle never to proceed to a higher dose before the patient has easily tolerated the present one you will be on safe ground. Accepting this method of giving the doses, the following are convenient increases after any dose is tolerated. If you have commenced with 0·05 c.cm. go on next to 0·075 c.cm., 0·1 c.cm., 0·15 c.cm., 0·2 c.cm., 0·3 c.cm., 0·5 c.cm., 0·7 c.cm., and 1·0 c.cm. These increases can always be varied according to the sensitiveness or otherwise of the patient. When the dose of 1·0 c.cm. has been reached, I believe the immunity lasts for at least one year, and if inoculations are repeated again in a year's time, it may be possible to immunise an originally sensitive person by giving three inoculations only.

(3) With regard to the composition and method of preparation of a vaccine, Dr. Simey suggests that specimens of sputum and "cultures" (I presume he means swabs) from the throat and nasopharynx should be sent to a pre-arranged laboratory by a certain date. I do not believe that this is the best way; probably most of the more chronic post-nasal catarrhs are due to either a pneumococcus, micrococcus catarrhalis, or streptococcus, and while there is great value in obtaining an autogenous vaccine for chronic cases, these organisms are of a lower virulence than those where there is pyrexia. A pneumococcus from a pneumonia case makes a far more potent vaccine than a pneumococcus from a chronic catarrh.

If pathologists can provide us with a prophylactic vaccine made from acute cases and made up of two types of pneumococcus as well as *M. catarrhalis*, streptococcus, *B. pfeiffer*, *B. pneumoniæ*, and *B. septus*, I believe that it will be far more effective as a prophylactic than if one is made up from the chronic cases. I do not know how far pathologists subculture in making up their stock vaccines; but it stands to reason that the less subculturing there is the more nearly will the organism correspond in its toxin to the organism growing on the mucous membrane. I presume that pathologists would always use blood in the medium when culturing a streptococcus; and is it possible that organisms grown on nasgar instead of agar make a more potent vaccine? I believe vaccines keep potent more than four months if kept in concentrated form.

I am, Sir, yours faithfully,

Oxford, Dec. 14th, 1925. Henry T. Gillett.

GANGRENOUS APPENDICITIS:

THE INITIAL SYNDROME.

To the Editor of The Lancet.

Sir,—Can one recognise, at the beginning of the illness, a class of appendicitis which calls for early operation to anticipate the certain onset of gangrene and perforation? I think so.

The public is aware and the practitioner knows that there are cases of appendicitis which, coming on suddenly and with acute symptoms, may and do end in resolution under medical treatment within 48 hours. The medical man called to attend an early condition which he suspects to be due to an acutely inflamed appendix finds himself in a very responsible position. He may elect to wait upon events and thereby incur disaster, or he may risk the confidence of his client by insisting upon an immediate operation. In this dilemma, what data are available to enable one to come to a conscientious decision?

In these circumstances I rely on what I have called the epigastric syndrome. This is a group of signs to be met with quite at the beginning of the gangrenous form of appendicitis. It is well marked during the first six hours and well in advance of the classic signs in the right iliac region. The patient—a child or young adult most commonly—complains of violent pain referred to the epigastrium. There is usually vomiting and the knees are not drawn up. An abdominal examination shows marked tenderness localised to the left upper epigastric region, with cutaneous hyperæsthesia within the same limits. The upper segment of the left rectus muscle is in a state of contraction and feels rigid to palpation. The right iliac region, on the contrary, betrays neither swelling, rigidity, tenderness, nor hyperæsthesia at this stage of the process. The temperature is often only slightly raised—99°–100° F.—and may become normal again as the syndrome passes. The pulse is a more reliable guide—90–120—and either does not decline with the fall of temperature, or may become progressively faster, and shows increasing tension. The duration of the syndrome varies ; it is most apparent during the first six hours of the attack, but it may still be recognisable in part so long as 18 or 19 hours after the beginning of epigastric pain. The last element to disappear is the tonicity of the left rectus.

I recently saw a case of gangrenous appendicitis in a boy of 12 years with a history of intense pain in the epigastrium together with vomiting. The temperature at the onset was 100° F., falling to 99° 12 hours later ; the pain was then passing off and the vomiting had ceased. When seen in consultation 18 hours after the commencement of the illness, there was no abdominal pain in any region, the temperature was normal, and the child was anxious to eat. He was apparently well, and that was the opinion of the parents. But there was still tonicity of the left rectus present in the upper segment, the pulse was 120, and there was the clear history of the rest of the syndrome. As yet there were absolutely no right iliac phenomena and no pain or tenderness in any region of the abdomen. Still, an immediate operation revealed an acutely inflamed appendix of the thickness and length of an adult index finger with a patch of gangrene 1 cm. from the tip.

As regards the ætiology of the syndrome, I have attempted to explain elsewhere[1] why signs and symptoms referable to the greater curvature of the stomach should be caused by a superacute gangrenous form of appendicitis.

The practical point is that the syndrome is transient. This being so, it is important for the family medical adviser to observe and to recognise the epigastric syndrome at the beginning of an attack, since to my mind it is a definite warning of the gravity of the process, and is in itself a formal indication for immediate operation. I would point out that the syndrome is almost never observed in the hospital wards—unless among the personnel—since the patient is seldom admitted early enough. But in general practice the syndrome can be recognised, and when present enables the medical attendant to decide definitely against temporising.

I am, Sir, yours faithfully,

R. M. Rowe,

Surgeon in Charge Out-patient Dept.,
French Hospital, London, W.C.

Dec. 14th, 1925.

AIR EMBOLISM DURING FALLOPIAN INFLATION.

To the Editor of The Lancet.

Sir,—Air inflation of the Fallopian tubes has become firmly established as a means of investigating cases of sterility, and the chief contra-indication is any evidence of pelvic inflammation ; apart from this the time of the menstrual period must be carefully avoided and the patient should be a suitable candidate for pregnancy. In a paper read before the Gynæcological Section of the Royal Society of Medicine on March 5th, 1925, I gave it as my opinion that air embolism must be regarded as one of the dangers, more particularly in those methods which employ high pressures such as 200 mm. Hg and over. At that time I had not seen or heard of a report of such a case ; however, on Oct. 15th last I encountered one which fortunately did not terminate fatally.

Mrs. A., aged 24, married five years, with scanty and irregular menstruation, came under observation for sterility. The usual examination and procedure showed that she had a small uterus, and the husband was normal. I determined to ascertain whether her Fallopian tubes were patent, and having arranged a date which fell in between periods, she was given glycerine plugs to be applied to the cervix on the two nights preceding the test. On Oct. 15th she was placed on the couch in the Trendelenburg position and the hollow dilator passed into the uterus, the bulb being attached to it. The pressure was gradually raised to 150 mm. Hg approximately. The patient complained of some pain in the pelvis, but no air escaped into the peritoneum ; the pressure was maintained for a few seconds when she became very restless, throwing her head about from side to side. Her breathing had become difficult and she was cyanosed, but was able to answer when questioned. Her condition grew worse and she became unconscious with slow and shallow respiration ; the pulse could be detected at the wrist, but was weak and small. The heart sounds were heard clearly but faintly, and no abnormal sounds could be detected. The corneal reflex was lost and the limbs were completely relaxed. She remained in this condition for about 20 minutes and then slowly regained consciousness. She was admitted to hospital and with the aid of cardiac stimulants recovered fully and was discharged the next morning.

I have no doubt that this was a case of air embolism, and it corresponds fairly closely with cases reported by K. V. Trubshaw,[1] R. S. Roper,[2] and A. Fullerton [3] after urethroscopy. I think the reason the symptoms were not more severe was due to the small quantity of air insufflated and the comparatively low pressure employed, and secondly to the immediate suspension of the inflation and withdrawal of the tube, thus promptly lowering the pressure and preventing the escape of any more air into the vessels. The symptoms were entirely cerebral and there was no indication of frothing or churning in the heart, therefore the air-block probably occurred in the capillaries of the brain. There was no history of fits in the patient herself nor in the family history, the urine was normal, and the vessel walls were healthy. The possibility of air embolism suggests the importance of air inflation being carried out at a time remote from the menstrual period and in the absence of uterine hæmorrhage, and secondly it is of great importance that the uterine cannula should be free in the uterine cavity and not buried in the wall of the uterus, when one or other or both of the following results would ensue : (1) the inflation would be negative, (2) there would be a grave risk of producing air embolism.

I am, Sir, yours faithfully,

Sidney Forsdike, M.D., F.R.C.S.,

Surgeon to Hospital for Women, Soho-square, W.

Dec. 8th, 1925.

THE TREATMENT OF RHEUMATIC AFFECTIONS BY INTRAVENOUS INJECTIONS OF SODIUM IODIDE AND SALICYLATE.

To the Editor of The Lancet.

Sir,—For several years past I have been treating rheumatic and other affections by intravenous injection. 15 gr. of (natural) sodium salicylate are boiled in a test-tube with 20 c.cm. of distilled water and 15 gr. of sodium iodide are added. I use a 20 c.cm. record syringe with eccentric nozzle and a sharp needle of No. 17 bore. The injection may be given in the consulting-room and there is usually no reaction. Occasionally there may be a slight feeling of coldness after about half an hour, which passes off in a few minutes. I have never seen thrombosis.

Improvement after injection is rapid and may be dramatic. In a case of acute sciatica within two minutes of the injection the patient could lift his thigh and walk across the room. Two days afterwards there was still tenderness on pressure over a certain place in the course of the nerve which disappeared after a second injection. On the fourth day the patient played a full round of golf. Some years ago I gave one injection to a Parsi doctor who had suffered from sciatica for six months ; within half an hour the pain disappeared and never returned. Dr. R. S. Bernard, of Sidmouth, tells me that he has just cured a chronic case of sciatica of four years' duration with two injections and that he is using this method largely for obstinate rheumatic affections. I am treating two cases of osteo-arthritis in this way at present and they are delighted with the relief afforded.

I think these drugs, when given by the mouth, undergo changes which prevent them from acting in the way they do when injected intravenously.

I am, Sir, yours faithfully,

F. J. W. Porter,

Major, R.A.M.C. (ret.).

Budleigh Salterton, S. Devon, Dec. 12th, 1925.

GLYCOSURIA AND LIFE INSURANCE.

To the Editor of THE LANCET.

SIR,—I wish to call attention to the following case. A healthy man, of wiry physique and clear family and personal history, was recently totally rejected by a well-known insurance company on account of alleged glycosuria, the urine having been tested at the office by boiling with a blue solution, and the remainder of the specimen poured down the sink. He was subsequently sent to me by his own medical adviser, when I estimated the sugar content of both blood and urine, after a meal containing a very large quantity of carbohydrate and sugar. The urine contained 0·08 per cent. and the blood 0·101 per cent. of sugar respectively. Not only, therefore, was this man not a diabetic, but his renal threshold and blood-sugar content being lower than normal, he was, if anything, a better risk in regard to his carbohydrate metabolism than the normal man. These facts were given to the company, who simply retorted that they intended to abide by their decision. The injustice of this procedure is evident, especially as the patient's prospects in regard to assurance in another company are prejudiced by his having to disclose his previous rejection.

What remedy has the man against this autocratic ignorance? I should be glad to know.

I am, Sir, yours faithfully,
A. KNYVETT GORDON, M.B.

Bedford-square, W.C., Dec. 14th, 1925.

LIPIODOL IN BRONCHO-PULMONARY DISEASE.

To the Editor of THE LANCET.

SIR,—The value of lipiodol in the diagnosis of broncho-pulmonary conditions and its possibilities in treatment are now being widely recognised. Simplification of any technique for introducing the oil into the bronchi is therefore of the greatest importance. The reports that I have read deal with methods involving puncture of the trachea or the passing of a bronchoscope, but I would point out that it is easily possible in the great majority of adult patients to introduce the lipiodol by means of an ordinary laryngeal syringe without inflicting upon them the very severe discomfort of a bronchoscope. I have practised this at the Royal Chest Hospital and found that after anæsthetising the larynx the patients will tolerate the introduction of lipiodol satisfactorily, and that by making them incline to one side or the other the oil can be made to run into both sides of the lung. It would obviously be very difficult, especially in this country, to persuade patients to accept the repeated passage of a bronchoscope under a local anæsthetic, and there are many who would not tolerate it even the first time.

I am, Sir, yours faithfully,
A. M. ZAMORA.

Devonshire-place, W., Dec. 2nd, 1925.

GLYCERINE AS A LYMPHAGOGUE.

To the Editor of THE LANCET.

SIR,—With reference to your report of a paper read by me on Puerperal Infection at the Section of Obstetrics, Royal Society of Medicine (THE LANCET, Dec. 12th, p. 1229), the sentence "The mixture he used was a 10 per cent. solution of tincture of iodine in glycerine, the iodine promoting the flow of lymph into the cavity of the uterus," should read "The mixture he used was a 10 per cent. solution of tincture of iodine in glycerine, the iodine helping to stimulate uterine contractions." My whole paper was on the effects of producing a flow of lymph into the cavity by using glycerine, the iodine merely being introduced as a stimulant.

I am, Sir, yours faithfully,
H. J. PHILLIPS.

Oldham, Dec. 14th, 1925.

Obituary.

JOHN E. ESSLEMONT, M.B., CH.B. ABERD.

THE death is announced at Haifa of Dr. John Esslemont, who was well known to the medical profession in many capacities, though for the last two or three years the state of his health had prevented him from practising and had necessitated his residence abroad, much of his life lately having been spent in Palestine.

John Esslemont was born at Fairford Cults in 1873, and graduated with distinction in medicine at the University of Aberdeen. He gained the Philip Research Scholarship in 1898 and proceeded to post-graduate work at Berne and at Strassburg. On return to Aberdeen he became assistant to the late Prof. J. T. Cash, the well-known professor of materia medica in that university. But at that early stage his professional career was interfered with by his health. He was forced to leave Aberdeen, and for some seven or eight years he travelled for his health, with intervals of practice, in Australia and South Africa—he was at different times resident surgeon at the Ararat Hospital, Victoria, Australia, and acting district surgeon at Kroonstad, South Africa. In 1908 he returned to England and became medical superintendent at the Home Sanatorium, West Southbourne, Bournemouth. During the 15 years which he held that post he became known as an ardent worker for the prevention of tuberculosis, his published articles including contributions to THE LANCET upon sanatorium treatment and to other medical and scientific journals upon the possible eradication of tuberculosis. He was a strong advocate of the formation of garden cities for the victims of tuberculosis, while another subject on which he thought and wrote much was the institution of a State medical service. In the last years of his life Dr. Esslemont became deeply interested in a religious movement having its rise in Persia, and some two years ago he wrote a full account of the tenets of this cult with the result, it is understood, that in the United States many adherents were attracted to it.

The medical profession has lost in Dr. Esslemont an interesting man, highly equipped on many sides of medicine and medical politics, and possessed of unusual intellectual gifts.

HILDA GORDON JAMESON, M.B., CH.B. BIRM.

WE regret to announce the death of Dr. Hilda Gordon Jameson at the early age of 26. Miss Jameson was educated at the Westbourne Council School, where she won a borough scholarship, after which she studied at Bournemouth College and later at the University of Birmingham. Here she took the degree of Bachelor of Science at a very early age and graduated with the M.B., Ch.B. in 1923, securing the gold medal in clinical surgery. She was appointed junior medical officer at the Birmingham City Fever Hospital and held appointments also at the Women's Hospital, Sparkhill. She was then elected senior house surgeon at the Children's Hospital, Western Bank, Sheffield, where her premature death occurred from pneumonia after a week's illness. Miss Jameson had started her career so well that her death at its outset must be regarded as a distinct loss to the medical profession, while general sympathy will be extended to her family.

GEORGE PADDOCK BATE, M.D. BRUX., F.R.C.S. EDIN., C.B.E.

THE death of Dr. Paddock Bate, by which our profession has lost one of its oldest practitioners, occurred on Dec. 1st, on the eve of his eighty-second birthday, at his residence in Hackney. He was a fine example of a practitioner whose knowledge of hygiene kept abreast of the science, and who developed into an important sanitary authority. A student and prizeman at Westminster Hospital, he qualified over 60 years ago as M.R.C.S. Eng., taking later the F.R.C.S. Edin. and the M.D. Brussels. He carried on a large general practice, and was also divisional surgeon of the J Division of the Metropolitan Police, a certifying factory surgeon, medical referee under the Workmen's Compensation Act, and an examiner in sanitary science to the Civil Service Commissioners. He was appointed medical officer of health for Bethnal Green nearly 50 years ago, and held the appointment until 1919, his position as a sanitary officer being recognised by his election to the presidency of the Society of Medical Officers of Health. He was an expert microscopist, and throughout his life spent much of his spare time in microscopic studies. He was also an expert worker with the lathe, turning in metal and wood, and had a real flair for the comprehension of intricate machinery. His favourite recreation was chess, and he was one of the original members of the Four-handed Chess Club. He held his post of certifying factory surgeon for the exceptionally long period of 35 years, and as far as one thing more than another in his useful career may be considered to have gained him the distinction of C.B.E., it was the thoroughness with which he discharged his factory work. He was also surgeon-lieutenant to the 5th Battalion of the Rifle Brigade.

Dr. Bate married Elizabeth, the daughter of the late Mr. Thomas Farr, and one of his sons, Dr. John Bate, succeeded him in his practice.

Medical News.

University of London.—At examinations held recently the following candidates were successful:—

THIRD (M.B., B.S.) EXAMINATION FOR MEDICAL DEGREES.

Honours.—Hannah Billig (*a*), London Sch. of Med. for Women; Roland H. Boggon (*d*), St. Thomas's Hosp.; Margaret Du Boulay Evans (*e*) and Alice M. C. Macpherson (*b*), London Sch. of Med. for Women; Walter R. Spurrell (*b*, *d*, University Medal), Guy's Hosp.; William A. Taylor (*a*), London Hosp.; and Paul B. Wilkinson (*a*, *d*), King's Coll. Hosp.

(*a*) Distinguished in Medicine. (*b*) Distinguished in Pathology. (*d*) Distinguished in Surgery. (*e*) Distinguished in Midwifery.

Pass.—Agnes L. Adam, London Sch. of Med. for Women; Arthur J. Amor, Middlesex Hosp.; Roland G. Anderson, St. Bart.'s Hosp.; Geoffrey Anderton, St. Mary's Hosp.; Colin B. Andreae, Guy's Hosp.; Kathleen J. Atkinson, King's Coll. Hosp.; Diana J. K. Beck, London Sch. of Med. for Women; Margaret A. L. Buckner and Dorothy M. Campbell-Meiklejohn, Univ. Coll. Hosp.; Enid A. Ceiriog-Cadle, London Sch. of Med. for Women; Florence C. Churcher, Univ. Coll. Hosp.; Eileen M. Clarke, Vera E. Claxton, Marian B. Coleman, and Dorothy Collishaw, London Sch. of Med. for Women; Anthony B. Cowley, St. Bart.'s Hosp.; Donald P. Crawford, St. Thomas's Hosp.; Reginald N. Curnow, St. Bart.'s Hosp.; Reginald Y. Dawbarn, University of Liverpool; Mostafa Dia, St. Mary's Hosp.; Ethel Downing, London Sch. of Med. for Women and St. Mary's Hosp.; David M. B. Evans, Charing Cross Hosp.; Desmond W. G. Faris, London Hosp.; Helen E. Fergusson, Charing Cross Hosp.; Cyril F. Fernando, Univ. Coll. Hosp.; Geoffrey R. Ford, Guy's Hosp.; Donald Frost, London Hosp.; Cecil P. R. Gibson, St. Thomas's Hosp.; George S. Hale, St. Bart.'s Hosp.; Frederick J. S. Hall, St. Mary's Hosp.; Kathleen M. D. Harding, London Sch. of Med. for Women and St. Mary's Hosp.; Noel G. Harris, St. Thomas's Hosp.; Constance E. Harrison, London Hosp.; Freda K. Herbert, King's Coll. Hosp.; Margaret R. Herford, St. Mary's Hosp.; Leslie G. Housden, Guy's Hosp.; John C. Hoyle, University of Manchester; Marjorie B. Hubert, London Sch. of Med. for Women and St. Mary's Hosp.; Edward C. Hudson, London Hosp.; Dorothea A. C. Hunt and Adèle H. Jacob, London Sch. of Med. for Women; Maurice E. M. Jago, Guy's Hosp.; Marjorie H. James, London Sch. of Med. for Women; Herbert M. R. Jones, Middlesex Hosp.; Kathleen M. Lankester, London Sch. of Med. for Women; Herbert Lord, Univ. Coll. Hosp.; Catherine B. McArthur, London Sch. of Med. for Women; Douglas G. Martin, St. Bart.'s Hosp.; Cecil P. Miller, St. George's Hosp.; Geoffrey O. Montgomery and Eileen S. Morris, Univ. Coll. Hosp.; David C. Mundy, University of Birmingham; Eric E. Neser, Guy's Hosp.; Frances C. Nicklin, London Hosp.; Muriel L. M. Northcote, London Sch. of Med. for Women; Maurice C. O'Connor, St George's Hosp.; Milroy A. Paul, King's Coll. Hosp.; Philip R. Peacock, Middlesex Hosp.; Marie Pedersen, London Sch. of Med. for Women; George H. Pitt, Guy's Hosp.; Thomas W. Preston, King's Coll. Hosp.; Montague D. Rawkins, St. Bart.'s Hosp.; Dorothy M. Rees and Nellie H. Reynolds, King's Coll. Hosp.; Eric W. Riches, Middlesex Hosp.; William G. Roberts, Guy's Hosp.; Thomas Robson, St. Thomas's Hosp.; William F. Roper, Guy's Hosp.; William H. Royal, University of Bristol; Navroji K. Sahiar, Grant Medical Coll. and Univ. Coll. Hosp.; Katharine F. E. Sanders, King's Coll. Hosp.; Stephen J. Scurlock, London Hosp.; Mung Bing Seng and Cyril Shepherd, Guy's Hosp.; Kenneth A. Soutar, St. Thomas's Hosp.; Joshua Stein, Univ. Coll. Hosp.; Ruby O. Stern, Charing Cross Hosp.; Leanagé Don John Telesphor and Alan K. Thomas, Univ. Coll. Hosp.; George W. R. Thomson, St. Thomas's Hosp.; Jean S. Thomson, London Sch. of Med. for Women; William G. Thwaites, St. Thomas's Hosp.; Beatrice E. Turner and Bertha Turner, London Sch. of Med. for Women; Neville A. A. van Buuren, Univ. Coll. Hosp.; Edward G. L. Walker, St. Thomas's Hosp.; John H. M. Walker, Univ. Coll. Hosp.; Helen D. Watson, London Sch. of Med. for Women; Mary A. Wiles, King's Coll. Hosp.; and Muriel M. Yates, London Sch. of Med. for Women and St. Mary's Hosp.

The following students have passed in one of the two groups of subjects:—

Group I.—Roderick T. Bannister, St. Bart.'s Hosp.; John R. Blazé, Ceylon Medical Coll. and Univ. Coll. Hosp.; Margaret H. Brown, Charing Cross Hosp.; Dorothy Durance, London Sch. of Med. for Women; William Fletcher-Barrett, St. George's Hosp.; Edith L. Gould, London Sch. of Med. for Women; Francis H. K. Green, St. Bart.'s Hosp.; Kempton P. Hare and Dorothy M. Howse, Univ. Coll. Hosp.; Ruth T. Hurnard, London Sch. of Med. for Women; Iorwerth H. Jones, Charing Cross Hosp.; Ambrose J. King, London Hosp.; Nora M. Leesmith, St. Mary's Hosp.; Gwynedd M. E. Olive and Catherine E. Orr-Ewing, London Sch. of Med. for Women; Howard L. Peake, Guy's Hosp.; John Pearce, Westminster Hosp.; Charles E. Pearsons, St. Bart.'s Hosp.; Elsie E. A. Ridley, London Sch. of Med. for Women; Aaron G. Silver, Middlesex Hosp.; Norman R. Smith, St. Thomas's Hosp.; Kenneth H. Southall, Univ. Coll. Hosp.; Frederick O. T. Strange, King's Coll. Hosp.; Herman Treissman, St. Bart.'s Hosp.; Kathleen E. Tresilian, London Hosp.; Reginald L. Waterfield and William S. Whimster, Guy's Hosp.; Emily A. C. Wilson, Charing Cross Hosp.; and Jessie Wiltshire and Ada R. Winter, Univ. Coll. Hosp.

Group II.—Harold C. Beccle and Louis F. Beccle, Guy's Hosp.; Philip S. Bell, Westminster Hosp.; Samuel Berman and Eric H. J. Berry, Guy's Hosp.; Frank A. Bevan and Ernest J. Blackaby, St. Bart.'s Hosp.; Margery G. Blackie, London Sch. of Med. for Women; Louis N. R. Comty, London Hosp.; Anne A. Craig and Victoria M. Crosse, London Sch. of Med. for Women; Evelyn J. Curtis, King's Coll. Hosp.; Gweneth M. Daniel, Westminster Hosp.; David J. Davies, Middlesex Hosp.; Howell J. Davies, St. Mary's Hosp.; Thomas D. Deighton, St. Bart.'s Hosp.; Margaret H. Duncan, London Hosp.; Harry G. Estcourt, Middlesex Hosp.; William G. Evans, St. Mary's Hosp.; Duncan B. Fraser, St. Bart.'s Hosp.; Winefride M. Gibson, Charing Cross Hosp.; Agness H. S. Gray, London Sch. of Med. for Women; John G. Hamilton, London Hosp.; Helen M. Harris, London Sch. of Med. for Women; Frederick C. Haward and William E. Heath, St. Thomas's Hosp.; Thomas R. Hill, Guy's Hosp.; Richard C. Howard, St. George's Hosp.; Leslie I. Hyder, King's Coll. Hosp.; Amelia M. Ison, Charing Cross Hosp.; Herbert N. James, St. Mary's Hosp.; Isabel E. S. James, King's Coll. Hosp.; Robert O. Jones, Middlesex Hosp.; Frances M. Kenyon, King's Coll. Hosp.; Howel Lewis, Guy's Hosp.; Reginald H. Little, St. Thomas's Hosp.; James H. Macpherson, King's Coll. Hosp.; Joan G. Malleson, Charing Cross Hosp.; John P. Monkhouse, St. Mary's Hosp.; Mary A. Monro, London Sch. of Med. for Women; Margaret I. Neal, London Hosp.; John O. Oliver, St. Thomas's Hosp.; Stephen M. Power London Hosp.; Janet McL. Robertson and Constance G. Sloan, St. Mary's Hosp.; John S. Symons, London Hosp.; Josephine I. Terry, St. Mary's Hosp.; Janet Welch, London Sch. of Med. for Women; and John C. Young, Guy's Hosp.

Royal College of Surgeons of England.—An ordinary meeting of the Council of the College was held on Dec. 10th, Sir John Bland-Sutton, the President, being in the chair. Mr. Charles Herbert Fagge (Guy's Hospital) was re-elected, and Mr. Russell John Howard (London Hospital) was elected a member of the Court of Examiners in Surgery.—With reference to the resolution carried at the annual meeting of the Fellows and Members, the following reply was adopted: "The Council has fully and earnestly considered afresh, at ordinary meetings and at a specially convened meeting, the question of the direct representation of Members on the Council, and has arrived at the following decision. In view of the urgent need for greater facilities for carrying on the examination work of the College, the Council proposes to proceed with the application for a Supplemental Charter to effect some modifications of the existing arrangements and at the same time to remove inequalities in the status of men and women holding the Diplomas of the College. The Council has confined this proposed Supplemental Charter to points which it believes could not reasonably be regarded as controversial, and is not prepared to apply in this Charter for an alteration in the constitution of the Council of the College, having regard to the difference of opinion prevailing on that question."—Diplomas of Fellow were conferred upon 33 candidates as the result of the examination held from Nov. 19th to Dec. 3rd, for which 105 candidates presented themselves. Thirty-six were successful at the examination, but three—H. Burt-White

(St. Bart.'s), N. L. B. V. Eckhoff (Guy's), and A. C. Maconie (St. Bart.'s)—not having attained the requisite age are not entitled to receive the diploma. The following are the names and medical schools of the successful candidates :—

John B. Barnett, Birmingham and St. Mary's; Martin B. S. Button, London; George H. Caiger, Cambridge and St. Bart.'s; Jivan D. Dhruv, Bombay and St. Thomas's; Charles Donald, Aberdeen and London; Hugh Donovan, Birmingham; Keith M. K. Duff, Guy's; Norman Ll. Edwards, Manchester and St. Bart.'s; John D. Grierson, Edinburgh and London; Frank W. Harlow, Durham; Francis J. Jauch, Middlesex and London; Norman A. Jory, St. Bart.'s; Arthur R. Lister, Cambridge and London; Andrew C. McAllister, King's Coll.; Eric E. Mackay, Melbourne and London; Norman S. Macpherson, St. Thomas's; Leslie Morris, Manchester and St. Bart.'s; John A. Panton, Manchester and Guy's; Reginald T. Payne, St. Bart.'s; Andrew McK. Reid, Liverpool and London; Owen W. Roberts, King's Coll.; Clifford H. C. Searby, Melbourne and London; George S. Sinnatamby, Ceylon and St. Bart.'s; Archibald G. Smith, Glasgow and Middlesex; Francis A. R. Stammers, Birmingham; Edward P. Stibbe, Charing Cross; James W. T. Thomas, Cardiff and Middlesex; Trevor M. Thomas, Cambridge and St. Bart.'s; Guy L. Thompson, Cambridge and London; Basil M. Tracey, St. Bart.'s; Alfred S. H. Walford, Cambridge and St. Thomas's; Hugh A. B. Whitelocke, Oxford and King's Coll.; and Charles Paul Wilson, Middlesex.

Licences in Dental Surgery were also conferred upon 79 candidates who have passed the requisite examinations and have complied with the by-laws. The following are the names and schools of the successful candidates :—

G. Allen, London; F. L. Anthony, Royal Dental; S. D. Badman, London; I. A. Barlow, Guy's; M. A. Bassett, Royal Dental; Doreen E. Bath, Royal Dental; A. E. J. Berry, Manchester; C. B. Boyd, Guy's; J. M. W. Boyd, Liverpool; R. N. Bragg, Royal Dental; L. J. Brown, Guy's; J. M. Bruce, Royal Dental; W. S. Carey, Bristol; P. S. Clarence, Guy's; D. L. Collier, Univ. Coll.; L. C. Darch, Royal Dental; T. S. Davidson, Guy's; Ivy G. Dey, Royal Dental: E. F. S. Dodd, Guy's; O. B. Easom, Univ. Coll.; J. C. A. Edmonds, Royal Dental; C. H. Edney, H. Falk, M. Farwell, and G. C. Ferguson, Guy's; J. A. Flitcroft, Manchester; W. C. G. Ford, R. D. G. Gain, and P. Gerrard, Guy's; Florence A. Hagen, Univ. Coll.; E. A. Haigh, Manchester; R. H. Hancock, Guy's; F. C. Hatherill, Royal Dental; H. Hazell, Bristol; L. de P. Henriques, London; D. R. House, Bristol; J. E. Inman, Royal Dental; E. R. Irish, Guy's; L. C. Isbill, Royal Dental; H. A. Johnson, Birmingham; R. R. Jonas, London; H. D. Joyce and Mary M. Kelham, Royal Dental; H. D. Kendrick and J. W. Kingston, Guy's; Elsie E. Lennane, Royal Dental; J. Levi, Univ. Coll.; R. C. Lillicrap, Guy's; F. J. Lord and W. Martland, Royal Dental; W. I. Matthews, Liverpool; H. Metcalfe, Manchester; H. Middleburgh, London; V. R. Morgan, Birmingham; E. A. Moss and H. Myers, Guy's; Valda Isobel Neish, Royal Dental; B. W. C. New, Univ. Coll.; R. M. Phillips, Guy's; C. E. Place, London; A. W. Y. Price and T. L. Quinn, Royal Dental; R. E. Rix, Guy's; F. D. Robinson, Liverpool; W. R. Rowland-Hill, Guy's; R. B. Samolsky and G. M. Sanderson, Royal Dental; A. Schultz, London; B. M. Shaffner and J. F. R. Sheahan, London; F. W. M. Siems, Royal Dental; H. S. Smyth, Univ. Coll.; P. M. Taleyarkhan, Royal Dental; A. W. Thorne, Bristol; J. D. J. Visser and C. M. White, Guy's; G. C. L. Wildsmith, Royal Dental; S. Wood, Manchester; and E. C. Woodhead, Guy's.

University of Dublin, School of Physic, Trinity College.—At examinations held recently the following were the successful candidates :—

Final Medical Examination.

Part II., Medicine (M.B.).—*Charles R. Boland, *Seymour F. Heatley, *James W. Bowden, *Ernest E. Satchwell, Robert L. Forsyth, Ransome M. Allardyce, Derek St. Clair Mackenzie, Henry J. Roche, Arthur B. Brooks, Richard G. Keays, John H. M'Lean, Denis J. Cussen, Robert V. Franklin, James C. C. Boyle, Aileen Fair, George A. Miller, Wilfred Sinclair, William J. A. M'Mahon, Frances E. O'Connor, Mary C. Livingston, Charles E. M'Causland, Cicero G. Nel, Launcelot W. R. Haskins, William G. S. Maxwell, Mabel E. Brittain, Gideon J. Joubert, Dorothy A. M'Entire, Grace J. Rankin. Barend P. Pienaar, Wolsey C. Sloan, William R. G. Gallagher, Howard St. George M'Kenny, William J. Van Zijl, William Magowan, Mary S. Miller, William Russell, Elspeth V. D. Hewat, William G. Maule, Philip Coleman, Margaret W. Pike, Norah E. Fenton, Margaret E. Pedlow, Henrietta Armstrong, Jane D. Fulton, John Johnston, Patrick Wallace, and Charles H. Wilson.

Surgery (B.Ch.).—*William B. Roantree, *James E. M'Cauley, *Maiben A. W. Roberts, Philip B. Robinson, James W. Bowden, Jack M. Selkon, William J. A. M'Mahon, Grace J. Rankin, John E. Stokes, William G. S. Maxwell, James J. Cusack, Gladys M. A. Colquhoun, Elias Rakoff, Alexander D. M'Lean, Harry Nelson, Angel V. B. Crawford, Henry M. Nevin, George A. Walmsley, Robert A. J. Holmes-Ievers, Francis H. M'Kenna, John St. Clair, Wilfred Sinclair, William R. G. Gallagher, Kathleen M. Ball, Carol R. J. Boland, George G. McFarland, Philip Coleman, William O. Warrington, James C. C. Boyle, Aileen Fair, Philip F. Palmer, Margaret E. Pedlow, William J. Van Zijl, Cecil H. Keller, Daniel J. Roux, Denis J. Cussen, Francis V. Duke, Charles E. M'Causland, Jane D. Fulton, Elspeth V. D. Hewat, Dorothy A. M'Entire; Christopher Lord-Flood, Barend P. Pienaar, Patrick Wallace, William H. Coen, Margaret Hill, Frances E. O'Connor, Ahmed A. Shafik, and Harris Tomkin.

Midwifery (B.A.O.).—*Henry O. Clerke, *Robert E. Hadden, Arthur B. Brooks, Arthur J. Conlin, George S. Gardner, Kathleen I. Purdy, Gilbert T. L. Archer, Robert A. J. Holmes-Ievers, Thomas J. W. Keown, Robert H. Mitchell, Desmond Blewitt, Roy K. Carson, Arthur R. Gray, John C. T. Sanctuary, Edward H. Harte, George E. Dodds, James F. MacMahon, Margaret H. Donaldson, Johan N. S. Gouws, Silver Margaret E. Deane-Oliver, Richard T. P. Tweedy, Annette K. Wood-Martin, Thomas F. M. Woods, Victor G. Horan, Andrew E. A. O'Byrne, George W. H. Townsend, Cicero G. Nel, Arthur N. B. Odbert, Ernest H. Hall, Myer Hoffman, Isabella K. M'Neilly, Edward W. Bingham, Gerald V. A. Griffith, Daniel A. O'C. Quinlan, Victor St. George Vaughan, Herbert A. Brittain, Menzies L. M'Cauley, Mabel E. Brittain, Kathleen R. Byrne, James G. M'Dowell, Donal B. O'Sullivan-Beare, Lionel B. Somerville-Large; and Robert C. U. Warrington.

* Passed on high marks.

Final Dental Examination.

Dental Surgery and Pathology; Dental Mechanics and Metallurgy; Orthodontics.—William G. Martin, Frederic D. Matthews, George A. Cowan, Robert H. McKeag, and Maurice C. Cowan.

University of Oxford: ***Radcliffe Travelling Fellowship*, 1926.**—An examination for a Fellowship of the annual value of £300, and tenable for two years, will begin on Feb. 16th, 1926. The examination will occupy four days. Papers will be set in physiology, pathology, and preventive medicine, and a subject will be proposed for an essay. There will also be a practical examination in pathology. Candidates must have passed all the examinations required by the University for the degree of Bachelor of Arts and for the degree of Bachelor of Medicine. They must not have exceeded four years from the time of passing the last examination required for the degree of Bachelor of Medicine. The successful candidate must before election declare that he intends to devote himself during the period of his tenure of the Fellowship to the study of medical science and to travel abroad with a view to that study. Intending candidates should send their names, addresses, qualifications, &c., to the Regius Professor of Medicine, University Museum, on or before Feb. 3rd.

Old Epsomian Club.—The annual meeting was held at the Trocadero Restaurant on Dec. 10th, followed by the annual dinner. The routine business of the meeting showed that the club was in a flourishing condition, over 50 new members having joined during the past year. The dinner was attended by nearly 100 members, and a most pleasant evening resulted. Amongst the guest present were Sir Humphry Rolleston and Mr. Bernard Lamb, secretary of Epsom College. During the dinner a presentation was made to Mr. S. Maynard Smith of a George II. cream jug, in recognition of his services as hon. secretary of the club during the years 1919–24, during which time the club was entirely reconstituted.

North-East London Post-Graduate College.—This college is holding a special post-graduate course at the Prince of Wales's General Hospital, N., from Jan. 11th to Jan. 23rd. This will consist of demonstrations of present-day clinical methods in the mornings from 10.30 A.M. to 1 P.M. each day, demonstration of groups of selected clinical cases from 2 to 2.45 P.M., general hospital work, clinics, operations, &c., in the various general and special departments of the hospital from 2.30 P.M. onwards, and a clinical lecture each day from 4.30 to 5.30 P.M. These lectures, which are free to members of the Fellowship of Medicine as well as to members of the college, will be given by Dr. Eric Pritchard, Prof. Hugh MacLean, Dr. Frederic Thomson, Dr. P. Manson-Bahr, Dr. F. G. Crookshank, Mr. H. W. Carson, Dr. C. E. Sundell, Mr. A. E. Giles, Dr. L. R. Yealland, and Mr. W. E. Tanner. On the two Saturday mornings there will be demonstrations of illustrative cases at the L.C.C. Mental Hospital, New Southgate, N., and at the North-Eastern Fever Hospital, St. Ann's-road, respectively. A syllabus of the course, with full particulars, may be obtained from the Secretary of the Fellowship of Medicine, at 1, Wimpole-street, W. 1, or from the Dean of the College.

Fellowship of Medicine and Post-Graduate Medical Association.—Several courses have been arranged under the auspices of the Fellowship of Medicine for January, 1926, including an intensive course in general medicine, surgery, clinical pathology, and the special departments from Jan. 11th to 23rd at the Prince of Wales's General Hospital. From Jan. 4th throughout the month a series of lecture-demonstrations on Tuesdays and Saturdays at 11 A.M. will be given at the Bethlem Royal Hospital on psychological medicine. On the same date at the West End Hospital there will begin a month's course in neurology, including lectures and demonstrations of selected cases, at 5 P.M. The North-Eastern Hospital will hold a three weeks' course in infectious fevers on Wednesdays at 2.30 P.M. and Saturdays at 11 A.M. A course in diseases of children will take place at the Queen's Hospital from Jan. 18th to 30th. Classes will be held from 10 A.M. throughout the day in the various departments. At the National Hospital for Diseases of the Heart a whole-day course will take place from Jan. 18th to 30th. It is intended to hold special demonstrations in clinical surgery weekly throughout the year, and those arranged for next month are: Jan. 11th, 5 P.M., Mr. J. P. Lockhart-Mummery at St. Mark's Hospital; 19th, 2 P.M., Mr. H. S. Souttar at the London Hospital; and the 27th, 2 P.M., Mr. Rock Carling at the Westminster Hospital. Subsequent announcements of these will appear in the Medical Diary. The Fellowship of Medicine has arranged a further series of lectures from January to March on general subjects of interest. The opening lecture will be given by Dr. Herbert Spencer on Abdominal Palpations in Pregnancy (with lantern demonstration), on Jan. 21st, at 5 P.M., in the Hall of the Medical Society of London. A copy of each syllabus and of the Fellowship General Course Programme may be obtained on application to the Secretary of the Fellowship, 1, Wimpole-street, London, W. 1.

LONDON HOSPITAL.—At a meeting of the Court of Governors held last week Lord Knutsford announced that an anonymous donor had given £50,000 for research work at the hospital. The Queen has consented to succeed Queen Alexandra as President of the Hospital.

SOCIETY FOR THE STUDY OF INEBRIETY.—A meeting will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, London, W., on Jan. 12th, 1926, at 4 P.M., when Dr. F. S. D. Hogg will open a discussion on Legislative Measures for the Control of Alcohol and Drug Addicts.

ROYAL SANITARY INSTITUTE.—This institute will celebrate its jubilee by holding an imperial congress in London from July 5th to 10th, 1926, over which Mr. Neville Chamberlain will preside. The opening meeting will be held in the Guildhall. Among those who will preside over the various sections and conferences into which the work of the congress will be divided are Sir William Pryke, Sir George Newman, Sir Charles Ruthen, Sir William Hardy, F.R.S., Sir Charles Wakefield, Sir William J. Collins, Mr. W. Phene Neal, Mr. G. W. Humphreys, and Dr. G. F. Buchan.

PEOPLE'S LEAGUE OF HEALTH.—The lecture programme for 1926 is now arranged and lectures will begin at the end of January next. Among those taking part in the courses are Sir Frederick Mott, F.R.S., Sir Maurice Craig, Sir Robert Armstrong-Jones, Dr. Bernard Hart, Dr. A. F. Tredgold, Dr. T. Beaton, Dr. R. H. Cole, Dr. W. A. Potts, Dr. Leonard Hill, F.R.S., Prof. R. H. A. Plimmer, Prof. E. Mellanby, Dr. M. J. Rowlands, Sir Henry Gauvain, Dr. P. C. Varrier-Jones, and Dr. F. E. Wynne. Lectures will be delivered at the house of the Medical Society of London, Chandos-street, W. 1, and at the Regent-street Polytechnic, London. Further particulars can be obtained from Miss Olga Nethersole at 12, Stratford-place, London, W.

ROSS INSTITUTE AND HOSPITAL FOR TROPICAL DISEASES, Putney Heath.—Sir Ronald Ross, Director-in-Chief of the Institute, sailed last week on the s.s. *Yorkshire* for Ceylon to set in motion a scheme which should, with the coöperation of all plantation companies, drive malaria out of the island. In certain parts of Malaya, Southern India, and Assam, groups of plantation companies are already dealing effectively with the cleansing of small areas. Sir Ronald Ross's intention is to deal with Ceylon as a whole, grouping plantation companies geographically, each group to be dealt with by a president malarial expert, who will carry out control measures adapted to the conditions peculiar of the particular locality, reporting from time to time to a central committee the progress made and difficulties encountered. Every facility will be given to individuals to take part in the campaign.

MEDICO-LEGAL SOCIETY.—The annual dinner of this society, held at the Holborn Restaurant on Dec. 11th, was well attended, professional women being present for the first time. Earl Russell, a past president of the society, took the chair in the absence of Lord Justice Atkin through illness. Lord Riddell proposed "Medicine and the Law," to which Sir StClair Thomson and Mr. T. R. Hughes, K.C., responded. Both foreshadowed a closer understanding between doctors and lawyers. Sir Ernley Blackwell, in proposing the "Medico-Legal Society," illustrated the mercifulness of the law by the fact that in a single year 75,000 convicted persons were set at liberty without punishment. Lord Russell, in reply, said that it was hoped in the next year or two to advance the scheme of a medico-legal institute for London, with laboratories and museum, the investigating side to be under the control of the Home Office, the teaching side to be associated with London University. Sir Bernard Spilsbury proposed "Our Guests," to which Dr. Vincent Dickinson and Sir A. W. Renton replied.

Lord Cave has been appointed a trustee of the Beit Memorial Fellowships for Medical Research.

THE Board of Governors of St. Mary's Hospital, London, have unanimously elected the Earl of Balfour to the office of President of the hospital.

LEEDS MEDICAL CHARITIES APPEAL.—The results of the appeal made in 1923 by Sir Edwin Airey, then Lord Mayor, has now been published. £90,327 was subscribed, all classes of the community contributing, and the money has been allocated as follows: the General Infirmary, £63,889; the Hospital for Women and Children, £10,003; the Public Dispensary, £9,935; and the Maternity Hospital, £6500. The first object of the appeal was to wipe off the hospital debts. This has been done, and the institutions receive also a valuable addition to their funds.

BRITISH LEGION: *British Serbian Units Branch.*—The annual dinner of this branch was held on Dec. 11th, Sir James Purves-Stewart, the President, being in the chair. Those present included Sir James Berry and Lady Berry, Dr. Alice Hutchison, Prof. Louise McIlroy, Lieut.-Colonel J. Johnston Abraham, Sir William Simpson, and Miss Flora Sandes, and all civil and military units were represented. Dr. Hutchison proposed the toast of the British Serbian Units Branch, Mr. C. R. Cooke-Taylor, chairman of the committee, replying. Miss Nina Boyle proposed the guests, Mr. Diouritch, minister plenipotentiary of the Serbs, Croats, and Slovenes in London, in reply, said that Serbia, like Great Britain, now wanted to forget the war and to live in peace. Bishop Keating and Sir William Simpson also responded for the guests. The health of the President was proposed by Prof. McIlroy and Sir James Purves-Stewart briefly replied.

DONATIONS AND BEQUESTS.—Mr. Henry Franc, of Fielden Park, West Didsbury, left £1000 each to the Manchester Royal Infirmary, to Ancoats Hospital and Dispensary, to St. Dunstan's Hostel for the Blind; £500 each to the Salford Royal Hospital, St. Mary's Hospital, Manchester, the Royal Manchester Children's Hospital, and the Manchester Victoria Memorial Jewish Hospital.—Mrs. Eleanor Emma de Wael, of Grange-gardens, Eastbourne, left £1000 to the London Hospital for naming a bed in perpetuity in memory of her son, Cecil Hubert.—Mr. James Shorrock, of The Beeches, Bowdon, Cheshire, left £2000 to the Manchester Royal Infirmary; £2000 to St. Mary's Hospital, Manchester; £1000 to the Altrincham Provident Dispensary and Hospital. His wife having predeceased him, a sum of £100,000 is to be divided between certain people and institutions, including the Manchester Royal Infirmary, the Altrincham Dispensary and Hospital, and St. Mary's Hospital, Manchester.—At a Court of Governors of the London Hospital on Dec. 9th, Lord Knutsford announced the receipt of a gift for research work of £50,000, from a donor who refused to permit his name to be mentioned. The donor has nominated a gentleman to represent him on a committee of three or four to decide how the money should be utilised.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Smoke Nuisances.

ON Thursday, Dec. 10th, Dr. SALTER introduced a Bill to amend the law relating to smoke nuisances and noxious and offensive gases.

Vivisection.

On Tuesday, Dec. 15th, Lieut.-Commander KENWORTHY presented a petition from 2567 persons resident in Torquay praying that the practice of vivisection might be discontinued.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 9TH.

Ill-health in the Navy.

Sir WALTER DE FRECE asked the First Lord of the Admiralty how many men had been discharged from the navy for ill-health in each of the last three years, including 1925; in how many cases these men had claimed that their disability was due to service; in how many cases these claims had been admitted and in how many rejected; and whether, in any case, the said applicants had had the right of appeal.—Mr. DAVIDSON (Parliamentary Secretary to the Admiralty) replied: The numbers invalided in the three years in question are:—1923, 1474; 1924, 1330; 1925 (from Jan. 1st to Nov. 30th), 1335. Any man invalided from the navy has the right of appeal to the Board of Admiralty, under whose directions the naval medical authorities would give his case careful and sympathetic consideration. As regards an appeal to any medical tribunal beyond the Admiralty, I would refer my hon. friend to the several replies already given in this House on the subject—e.g., on April 1st, Feb. 16th, and Dec. 15th last. I regret that the information asked for in the remainder of the question cannot be given without a detailed examination of the documents of over 4000 cases, for which no margin of staff is available.

Ill-health in the Army.

Sir Walter de Frece asked the Secretary of State for War how many men had been discharged from the army in each of the last three years, including 1925, for ill-health; in how many of these cases the men had claimed that their disability was due to service; in how many cases these claims had been admitted and in how many rejected; and whether, in any case, the said applicants had had the right to appeal and, if so, to whom.—Captain D. King replied: The number of men invalided from the army in each of the last three years ending on Sept. 30th have been 2920, 2673, and 2606 respectively. No statistics are available showing in how many of these cases the men claimed that their disability was attributable to service, but the number of cases in which disability was accepted as due to service were 373, 419, and 347 respectively. Applicants have no right of appeal against the decision of the Chelsea Commissioners. The Chelsea Commissioners are an independent body, who adjudicate upon the soldier's claim, and are not subject to the control of any Government department in administering the pension regulations.

Use of Toxoid in Schools.

Mr. Lindley asked the Minister of Health the names of the schools referred to on pages 57–60 of his report for 1924; whether toxoid was used at the B school as well as at the A school; whether the consent of the parents was obtained at the A school as well as at the B school; and where the toxoid was manufactured.—Mr. N. Chamberlain replied: The report referred to is the Report of the Chief Medical Officer of the Ministry. As regards the first and last parts of the question, I think it is undesirable in the public interest to state the names of these schools or of the laboratory where the toxoid was manufactured. The answer to the second and third parts of the question is in the affirmative.

THURSDAY, DEC. 10TH.

Institutional Treatment of Pension Patients.

Mr. Duckworth asked the Minister of Pensions the number of men who had been in continuous institutional treatment by his department since the war; and whether, with a view to possible speedier recovery, there was any transfer of such patients from one institution to another.—Major G. C. Tryon replied: I regret that I have no record of the number of cases which have been in receipt of continuous institutional treatment since their discharge from service. With regard to the latter part of the question, I may say that all cases in receipt of hospital treatment are subject to periodic inspection and report, and that special attention is given to those cases which have been for a prolonged period in receipt of this form of treatment, with a view to considering whether any other form of treatment or institution is more suitable to their condition.

Panel Doctors and Pension Patients.

Mr. Pielou asked the Minister of Pensions whether he was aware that the Ministry were referring disabled men for treatment to the panel doctor but, in some cases, refusing the recommendation of that panel doctor so far as the payment of treatment allowances was concerned; and whether he would see that due regard was paid by the Ministry to the treatment prescribed by the panel doctor in so far as it affected the treatment allowances regulations.—Major G. C. Tryon replied: I would remind my hon. friend that the conditions governing the grant of allowances under Article 6 of the Royal Warrant are not identical with those which determine certification for the purposes of health insurance, with which the insurance practitioner is concerned. For the purpose of the former allowances, certification by a medical officer of the Ministry is required under the terms of the Warrant. At the same time, any information which may be supplied by a panel doctor with regard to one of his pensioner patients is always taken into careful consideration in connexion with any certificate required to be given by an officer of the Ministry.

Reconsideration of Final Awards.

Mr. Pielou asked the Minister of Pensions the number of cases that had been recommended by local Ministry doctors for reconsideration by the correction of errors board; and the total number of such cases that had resulted in the final award being increased.—Major G. C. Tryon replied: I am unable to furnish statistics on the lines specified by my hon. friend. But I may say that up to Nov. 21st last 2550 cases had been dealt with by the Ministry. In 1402 of these cases a further grant had been made. In the remaining cases considered it had been found, either on local medical advice or otherwise, that there was no ground for disturbing the final award.

Area Deputy Medical Commissioners.

Mr. Montague asked the Minister of Pensions what was the number of medical officers holding the appointment of area deputy commissioner of medical services, and what was the average number of square miles in each area outside the Metropolis; and whether any deputy commissioner of medical services was responsible for more than one area as originally constituted under the War Pensions Act, 1921.—Major G. C. Tryon replied: The number of area deputy commissioners of medical services is 57, of whom five are stationed in the metropolitan areas. The square mileage of the districts covered by these medical officers is irrelevant to the question of their proper distribution which is made and, where necessary, varied in accordance with the distribution and needs of the ex-Service population. In the more densely populated districts, where the work is heaviest, the deputy commissioners are provided with assistants, who number 30 in all. The reply to the last part of the question is in the affirmative.

Pensioners in Mental Institutions.

Mr. Gibbins asked the Minister of Pensions what proportion of the 26,000 in receipt of treatment with allowances were inmates of mental institutions; what was the number of chronic cases which had been more or less under treatment since discharge; and whether, particularly in the case of neurasthenics, he would consider the possibility of awarding a good life pension, and release the men from treatment.—Major G. C. Tryon replied: About 6600 of the total number of cases under treatment are inmates of mental institutions. Apart from this class of case, there are a substantial number of men who have received prolonged periods of treatment since their discharge. Many of them—e.g., those suffering from paraplegia or severe cases of wound and injury—require constant medical attention and skilled nursing. Others, although happily not in this condition, are, in accordance with medical advice, receiving prolonged institutional treatment and care, combined, where possible, with occupation. It is not the intention of the Ministry that cases should indefinitely or unnecessarily remain in an institution, and where it is considered by my medical advisers that any case can more suitably be dealt with by discharge from institutional care, with an appropriate rate of pension, this course is adopted.

Lead Poisoning Among Pasters.

Mr. Robinson asked the Home Secretary how many cases of lead poisoning occurred among pasters engaged in the manufacture or repair of electric accumulators in the years 1921, 1922, 1923, and 1924 respectively; and whether any cases had been reported since the new code of regulations came into force on March 1st, 1925.—Sir William Joynson-Hicks replied: There were 5 such cases reported in 1921, 11 in 1922, 44 in 1923, and 42 in 1924. Since March 1st last there have only been 15 cases among pasters. The new regulations cannot be expected to have their full effect for a considerable time, but they appear to have already caused a substantial reduction in the number of cases.

Cases of Chemical Poisoning.

Mr. Robinson asked the Home Secretary how many cases of poisoning by carbon bisulphide, aniline poisoning, and chronic benzene poisoning had been reported since Feb. 1st, 1925; and what special steps were being taken by his department to diminish the risk of chemical poisoning.—Sir William Joynson-Hicks replied: Two cases of carbon bisulphide, and 30 cases of aniline poisoning have been reported, but no case of chronic benzene poisoning. Special steps are taken to diminish the risk by following up each case, and generally by the enforcement of the special precautions required by the Chemical Works Regulations of 1922. The whole subject is receiving special attention from the medical inspectors.

Medical Students and the Special Constabulary.

Mr. Scurr asked the Home Secretary whether he was aware that at a recent meeting of the medical students of London Hospital the dean of the students' guild stated that he had received a request from the Home Office that he should take steps to enrol the students of the hospital into a special branch of the special constabulary; that this action was taken in view of the possibility of industrial trouble in the spring; and that similar requests had been made to the deans of guild at St. Bartholomew's and Guy's Hospitals; and whether such request had been made by the Home Office, and the reason for the action.—Sir William Joynson-Hicks replied: I have not made any request such as the hon. Member suggests. The Commander of the

Headquarters Central Division of the Metropolitan Special Constabulary addressed an ordinary recruiting meeting of the students at the London Hospital last month, but I am informed that no statements as suggested in the question were made either by the commander or by the dean who introduced him to the meeting.

Epidemics and Closing of Schools.

Sir Hugh Lucas-Tooth asked the President of the Board of Education under what authority a county medical officer had the power to override the decision of the managers of a school, in a district infected with an epidemic, temporarily to close the school.—Lord E. Percy replied: I assume that my hon. friend is referring to public elementary schools. I am advised that Section 29 (1) and Section 29 (2) (*a*) of the Education Act, 1921, enable the local education authority to give directions to the managers of a school as to the days on which the school is to be open. On the question of closure on medical grounds, the authority would act, of course, upon the advice or with the approval of their medical officer. My hon. friend will find some useful information on the subject in the memorandum on closure of, and exclusion from school, issued jointly by the Ministry of Health and my department.

The Use of Luminal.

Mr. Scurr asked the Minister of Health what steps, if any, were taken by his department to draw the attention of the medical profession to the dangers arising from the use of the drug luminal, especially as, when used for the treatment of epilepsy, serious danger arose unless the treatment was continued although the epilepsy was cured.—Mr. N. Chamberlain replied: I am advised that the effects of the drug have been very fully discussed in the medical press, and in view of the amount of attention which it has received it seems justifiable to assume that those doctors who use it are well aware of its action and possible risks.

Diphtheria Mortality in West Bromwich.

Mr. Robert Richardson asked the Minister of Health why no reference was made, in the annual reports of the Chief Medical Officer of the Ministry of Health for the years 1922 and 1923, to the exceptionally high mortality and fatality from diphtheria which occurred in the county borough of West Bromwich in the years in question; whether any inquiry was made by his department in regard thereto and, if so, what special causes led to this exceptional incidence of the disease in this locality; how many of the cases were treated in hospital and how many proved fatal; and in how many of the cases treated in hospital was antitoxin administered and how many of such cases proved fatal.—Mr. N. Chamberlain replied: It is the fact that the mortality from diphtheria in West Bromwich was exceptionally high in 1922 and 1923, but the incidence was fairly constant throughout those years, and the occurrence presented no feature necessitating any special inquiry by my department or reference to the matter in the annual report of the Chief Medical Officer. The high incidence and fatality in 1922 were attributed by the medical officer of health to the fact that in the majority of cases medical assistance was not sought until the third or fourth day of the disease, and there was consequent delay in administering antitoxin. As regards 1923, the medical officer of health reported that more prompt recourse to medical assistance, which rendered earlier administration of antitoxin possible, had resulted in a reduction in the case mortality. In 1922, 96 cases were treated in hospital, of which 18 proved fatal; the figures for 1923 were 159 and 19 respectively. In all these cases antitoxin was administered.

Overcrowding in London Area.

Mr. Thurtle asked the Minister of Health if any statistics were available as to the number of rooms in the London County Council area which were occupied by four or more persons.—Mr. N. Chamberlain replied: The number of rooms in the administrative county of London occupied by private families at an average density of four or more persons per room was 18,847 at the census of 1921. No figures are available for any later date.

Inquiries into Conduct of Panel Doctors.

Lieut.-Commander Kenworthy asked the Minister of Health whether, as the National Health Insurance Act, 1924, required that he should exercise his judicial powers in particular cases through special tribunals, whether the committees of inquiry set up to consider whether the continuance of a practitioner on the medical list would be prejudicial to the service were such tribunals; and what other tribunals had been prescribed under Section 91 (*c*) of that Act.—Mr. N. Chamberlain replied: The inquiry committees in question are appointed in accordance with regulations made under Section 24 (2) of the National Health Insurance Act, 1924, and are not governed by the provisions of Section 91 of that Act. Regulations made under Section 91 provide for the submission of disputes of the kind referred to in Section 90 to a special body of referees. Apart from the body of referees constituted for this purpose, no tribunals have been set up under Section 91.

Lieut.-Commander Kenworthy asked the Minister of Health whether he was aware that a considerable section of insurance practitioners desired to be given a general right of appeal in the courts against his decisions; that this desire was recently voiced by a public conference of delegates representing not less than 5000 practitioners; whether he had refused to receive a deputation from that conference; and what steps he was taking to allay the widespread feeling of discontent which underlay the desire in question.—Mr. N. Chamberlain replied: The answer to the first part of the question is in the affirmative. As regards the second part, I have received the resolutions passed at the meeting to which the hon. and gallant Member refers, though I cannot share his estimate of its representative character. The reply to the third part of the question is in the affirmative, and the reason is that I have already discussed the matter with the Insurance Acts Committee of the British Medical Association, which represents the general body of insurance practitioners. As regards the last part, this question is engaging the attention of the Royal Commission on Health Insurance, and I do not propose to take any action pending their report.

FRIDAY, DEC. 11TH.

Death-rates Among Adults.

Colonel Day asked the Minister of Health the death-rate amongst adults, men and women separately, also that of children, occurring in those European countries of which statistics were available, also those occurring in Great Britain during the years 1922 and 1923, and to the last known date.—Mr. Neville Chamberlain replied: For England and Wales the figures asked for are as follows:—

Age groups.	Death-rates per 1000 living of each sex.					
	1922.		1923.		1924.	
	M.	F.	M.	F.	M.	F.
21 and over.	16·7	14·7	15·5	13·4	16·2	14·2
Under 5 ..	30·2	24·5	24·3	19·6	25·1	20·2
,, 10 ..	16·5	13·5	14·0	11·3	14·9	12·1
,, 15 ..	11·4	9·4	9·7	8·0	10·3	8·4
,, 20 ..	9·2	7·7	7·9	6·5	8·3	6·9
,, 21 ..	9·0	7·5	7·7	6·4	8·1	6·7

M. = Males. F. = Females.

With regard to Scotland, the hon. and gallant Member should address a question to the Secretary for Scotland. As regards other European countries, while in certain cases figures are available for the numbers of deaths during the years in question, no corresponding estimates of population appear to be available for the purpose of calculating mortality rates.

MONDAY, DEC. 14TH.

Cocaine Dens in India.

Colonel Day asked the Under-Secretary of State for India if there were at present any cocaine dens in the northern division of Calcutta, and the name of the deputy commissioner in charge of this division; and how long had he occupied that position.—Earl Winterton replied: Some information as to the illicit traffic in cocaine and the preventive action taken is given in the report of the Bengal Excise Department, extracts from which I shall be glad to have supplied to the hon. Member if he wishes. The reports do not contain the specific information asked for in the first part of the question, but special inquiry can be made if he so desires. The Deputy Commissioner of Police, Northern District, Calcutta, is Rai Purna Chandra Lahiri Bahadur, who was appointed on March 6th, 1918.

Poisonous Apple Tree Sprays.

Mr. Rennie Smith asked the Minister of Agriculture whether his attention had been drawn to the dangers of poisoning arising from the use of certain kinds of sprays on apple trees; whether such sprays were being used in this country; and whether he would take steps to warn fruit-growers as to sprays which entailed these dangerous consequences.—Mr. Guinness replied: I have received representations from time to time as to the possible risks involved by the use of poisonous washes on apple trees. Such washes are used in this country, but the applications are made so early in the season that the risk of any appreciable quantity of poison remaining on the apples when they are gathered is negligible. The results of an inquiry into this matter were published in the Ministry's *Journal* for September last, a copy of which I am sending to the hon. Member.

Mr. Rennie Smith asked the Minister of Health whether his attention had been drawn to the poisonous spraying of foreign apples imported into this country; what brands of apples were affected; and what steps he was taking to safeguard British consumers of apples.—Sir K. WOOD replied: Yes, Sir; as stated on June 25th last, the matter has been under the observation of my department for a number of years. My right hon. friend is sorry to say that recent analyses have shown the presence of increased quantities of arsenic on certain brands of imported Jonathans. The safeguarding of consumers is in the hands of the Port Sanitary and other local authorities, whom my right hon. friend is reminding of the necessity for strict supervision. He is, however, trying to arrange that measures shall be taken to effect the removal of the contamination before the apples are packed for export to this country.

Release of Asylum Patient.

Mr. ROBERT RICHARDSON asked the Minister of Health if he would cause inquiry to be made into the case of T. J. Hardwick, at present detained as an ex-Service patient in Chatham Asylum, Kent; was he aware that his mother was anxious to have him out on trial for a month under Section 55 of the Lunacy Act; that her own doctor had signified to the medical superintendent his willingness to look after the son, and that a suitable male nurse was available to take care of him while on trial, a course recommended by a member of the Board of Control; and would he take steps to see that no impediment was placed in the way of his temporary release on trial.—Sir KINGSLEY WOOD replied: My right hon. friend has made inquiries in this case. The power to grant leave on trial is vested by law in the visitors of the hospital on the written advice of the medical superintendent. The superintendent is, however, unable to advise the visitors that they should permit Mr. Hardwick to be absent on trial. A report made within the last few days shows that this is a dangerous patient, who is not fit at present to be discharged from institutional care. I would like to add that last year this patient was allowed out on leave in the care of his mother, but had to be brought back on the following day to the institution.

Constitution of the General Medical Council.

Lieut.-Commander KENWORTHY asked the Prime Minister if the Lord President of the Privy Council had been approached by any section of the medical profession with regard to the constitution of the General Medical Council; and what steps, if any, he had taken or proposed to take in this matter.—Major HENNESSY (Vice-Chamberlain of the Household) replied: The reply to the first part of the question is in the negative, and my noble friend, the Lord President of the Council, considers that the case for action, as suggested in the second part, does not, therefore, arise.

Powers of the General Medical Council.

Mr. BASIL PETO asked the Prime Minister whether he would consider the necessity of amending Sections 26, 28, and 29 of the Medical Act of 1858, in view of the obscurity of the procedure under the Act and the confusion of the powers of examining colleges and bodies and the General Medical Council, whereby persons whose names had been removed from the Register were required by the General Medical Council to prove that they possessed degrees of which they had been deprived, in consequence of the General Medical Council having removed them from the Register, before their names could be restored to the Register.—Major HENNESSY replied: I am asked by my noble friend, the Lord President of the Council, to state that he is informed that there is no difficulty in interpreting the sections of the Act of 1858 to which my hon. friend refers. It must be remembered that the General Medical Council cannot confer medical degrees or qualifications, nor can it annul such when once conferred. Moreover, it cannot place a man on the Register unless he possesses a degree or qualification. When, therefore, a practitioner has been deprived of his degree or qualification by the body which originally conferred it, that body must restore it before the General Medical Council can reverse its own previous decision.

Mr. BASIL PETO asked whether, when the General Medical Council removed any person from the Register for reasons given, the consequence was that the colleges or other examining bodies automatically withdrew that person's degree. If that were the case, how could such a person get on to the Register again, unless the original examining body acted in the matter.—Major HENNESSY replied that he must have notice of that question.—Mr. PETO pointed out that that was the original question on the paper.

Infant Mortality at Market Drayton.

Sir CHARLES OMAN asked the Minister of Health whether he was aware that the high infant mortality of Market Drayton still persisted and had persisted for 10 years or more; would he now publish the recommendations for its diminution made by the report of his medical inspector, omitting those which he considered confidential if there were any such; and, if not, would he send another medical inspector to inspect and report.—Mr. N. CHAMBERLAIN replied: I am aware that the infant mortality-rate in Market Drayton has generally been in excess of the average rate for the whole country, although this has not always been the case in the past ten years. As regards the second part of the question, I would refer my hon. friend to my previous answers on this subject. The county council are taking steps to provide a new infant welfare centre in this district, and the further inspection suggested in the last part of the question does not, therefore, seem to be necessary.

Treatment of Consumptives in Scotland.

Mr. SCURR asked the Secretary for Scotland whether he could state which local authorities in Scotland afforded sanatorium and other treatment to tuberculous persons without charge.—Sir J. GILMOUR replied: No local authority in Scotland, so far as I am aware, makes a charge to tuberculous patients or their relatives for sanatorium or other treatment provided by the authority.

TUESDAY, DEC. 15TH.

Tuberculosis Hospital near Bristol.

Captain GUNSTON asked the Minister of Health whether he was aware that the proposal of the corporation of Bristol to use Blaise Castle as a tuberculosis institution for advanced cases was strongly opposed by the inhabitants of Henbury, whose houses, school, &c., surrounded Blaise Castle, and would he have this matter further inquired into.—Sir K. WOOD replied: My right hon. friend has received a letter from the Henbury Parish Council objecting to this proposal. In the event of the Bristol Corporation applying for his approval to the use of the premises for the treatment of tuberculosis, this objection will be considered. My right hon. friend is advised, however, that there is no ground for considering that a properly conducted institution for the treatment of tuberculosis is in any way a danger to the health of the community among whom it is situated, and that no risk is incurred by living in the immediate neighbourhood of such an institution.

Institutional Treatment of Neurasthenia.

Mr. ROBINSON asked the Minister of Pensions the number of men in receipt of institutional treatment for neurasthenia, where the hospitals were situated, and what was the estimated total yearly cost of providing treatment for pensioners suffering from neurasthenia.—Major G. C. TRYON replied: The number of men in receipt of in-patient treatment for neurasthenia in the first week of the present month was 1809. The yearly cost of the treatment given in Ministry hospitals for this class of case is approximately £250,000. The following are the hospitals: Craigleith, Edenhall, Scotland; Castle Leazes, Newcastle; Harrowby Camp, Grantham; Saltash, Plymouth; Coombe Park, Bath; Ewell, Epsom; Orpington, Kent; Leopardstown Park, Dublin; and Craigavon, N. Ireland.

Disease Germs in Public Vehicles.

Colonel APPLIN asked the Minister of Transport whether he was aware that public vehicles were upholstered in rep, velveteen, and other soft and clinging material, and whether, as such material collected dirt and disease germs, and broadcasted them among the passengers, he would take steps to ensure the use of leather or other washable material in future.—Colonel W. ASHLEY replied: This is a matter for the individual licensing authorities, but I will bear in mind the suggestion that my hon. and gallant friend has made.

Deaths of Seamen.

Dr. WATTS asked the President of the Board of Trade whether he had received a resolution, adopted by the Council of the Royal Sanitary Institute, based on resolutions passed at a congress of that institution at Liverpool in July, 1924, to the effect that the classification in the Report of Deaths of Seamen, published by the Board of Trade, was antiquated and should be remodelled; and whether he was taking any steps in respect to this resolution.—Sir P. CUNLIFFE-LISTER replied: I have received a resolution from the Royal Sanitary Institute and also their detailed suggestions regarding the death statistics of seamen. The Permanent Consultative Committee on official statistics has appointed a special subcommittee to advise whether any alteration in the classification of these death statistics is necessary.

Pensions for Neurasthenia.

Mr. ROBINSON asked the Minister of Pensions the number of officers and other ranks that had been in receipt of pension for neurasthenia for four years or more; how many of these were in receipt of life pensions; and whether he would arrange for the men not in receipt of a final award to be boarded with a view to the award of life pensions, having regard to the psychological effect that a permanent pension would have on their disability.—Major G. C. TRYON replied: The number of pensions at present in payment for neurasthenia is about 32,000 of which about 12,000 have been awarded for life. Of the balance about 17,000 pensioners have been in receipt of pension for four years or more and I can assure the hon. Member that the possibility of making final awards in these cases is constantly kept in view in connexion with the medical re-examination of cases.

Appointments.

Gray, E. E. D., M.B., B.S. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Teddington District of the County of Middlesex.

University of Sheffield: Wilson, J. B. F., M.B., M.S. Lond., F.R.C.S. Eng., to one of the combined posts of Lecturer in Surgical Pathology and Assistant Curator of Pathological Museum.

Vacancies.

For further information refer to the advertisement columns.

Ascot, Heatherwood Hospital.—Res. Asst. M.O. £300.

Birmingham City.—Laboratory Attendant. £250.

Blackburn and East Lancashire Royal Infirmary.—Third H.S. £150.

Bombay, Gokuldas Tejpal Hospital.—Hon. P. and two Hon. S.'s.

Bristol General Hospital.—Hon. Asst. S. to Ear, Nose, and Throat Dept.

Durham, Holywood Hall Sanatorium.—Med. Supt. £850.

East London Hospital for Children and Dispensary for Women, Shadwell, E.—Morning Cas. O. At rate of £120. Also H.S. At rate of £125.

Elizabeth Garrett Anderson Hospital, 144, Euston-road, N.W.—Asst. Radiologist. £100. Also Anæsthetist. £5 5s.

Hospital for Sick Children, Great Ormond-street, W.C.—Res. Med. Supt. £300. Also H.S. £50.

Huddersfield, Royal Infirmary.—Jun H.S. £150.

Ipswich, East Suffolk and Ipswich Hospital.—H.P. and H.S.'s. Each at rate of £100.

Keighley, Victoria Hospital.—Res. M.O. At rate of £180.

London Temperance Hospital, Hampstead-road, N.W.—Cas. O. At rate of £120.

Manchester Ear Hospital, Grosvenor-square, All Saints.—Hon. Res. H.S. At rate of £150.

Manchester, Monsall Hospital for Infectious Diseases.—Jun. Med. Asst. £350.

Manchester, St. Mary's Hospitals.—Five H.S.'s. Each at rate of £50.

Middlesex Hospital, Mortimer-street, W.—Dental H.S. At rate of £50.

Norwich, Norfolk and Norwich Hosp.—Res. Anæsthetist. £150.

Plaistow Fever Hospital, E.—Second Asst. M.O. £200.

Plymouth, Didworthy Sanatorium, South Brent.—Res. M.O. £600.

Portsmouth Education Committee.—School M.O. £750.

Reading, Royal Berkshire Hospital.—Three H.S.'s. At rate of £150. Also Hon. Anæsthetist.

Royal Free Hospital, Gray's Inn-road, W.C.—Dist. Obstet. Asst. £100.

St. Mark's Hospital for Cancer, &c., City-road, E.C.—Anæsthetist. £25.

St. Mary's Hospital, W.—Asst. M.O. in charge of X Ray Dept.

Salisbury General Infirmary.—H.S. £150.

West London Hosp., Hammersmith-rd., W.C.—Hon. Obstet. Reg.

Westminster Hospital, Broad Sanctuary, S.W.—Obstet. Tutor and Registrar. £50.

The Secretary of State for the Home Department gives notice for a Medical Referee under the Workmen's Compensation Act for Falkirk District (Sheriffdom of Stirling, Dumbarton, and Clackmannan). Application should reach the Private Secretary, Scottish Office, not later than Jan. 5th, 1926.

Births, Marriages, and Deaths.

BIRTHS.

Hughes.—On Dec. 9th, at Woodville, Epsom, the wife of Alfred Morgan Hughes, *M.C.*, M.R.C.S., of a son.

Schaffter.—On Dec. 12th, at Isfahan, Persia, the wife of C. M. Schaffter, M.B., F.R.C.S.E., of a son.

Spero.—On Dec. 8th, at Lancaster Gate-terrace, W., the wife of Dr. G. E. Spero, of a son.

MARRIAGES.

Salisbury—Wright.—On Dec. 9th, at St. Mary's Church, Broughton, Lincs, Walter Salisbury, M.S., M.D. Lond., F.R.C.S. Eng., of Grimsby, younger son of Mr. and Mrs. F. G. Salisbury, of Bristol, to Constance Mary, only child of Mr. and Mrs. Wm. Wright, of Broughton Vale.

DEATHS.

Bishop.—On Dec. 13th, after short illness, at his residence, North Dene, The Park, Beckenham, Walter Beacall Bishop (of Alfred Bishop, Ltd.), aged 72.

Edwards.—On Dec. 4th, at 137, Withington-road, Whalley Range, Manchester, after long illness patiently borne, Emily Louisa Frances, the dearly beloved wife of the late John Edwards, M.R.C.S., L.R.C.P., late Senior Medical Officer, H.M. Prison Service.

Norbury.—On Dec. 10th, at "St. Margarets," Eltham, Sir Henry Frederick Norbury, K.C.B., M.D., F.R.C.S., Hon. Surgeon to the King, Inspector-General of Hospitals and Fleets, Royal Navy (retd.), aged 86.

Palgrave.—On Dec. 13th, Edward Francis Palgrave, M.R.C.S., F.R.C.P., Cheniston-gardens, Kensington, aged 49.

Ritchie.—On Dec. 10th, at Craigowan, Colinton-road, Slateford, Edinburgh, James Ritchie, M.D., in his 85th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE DIAGNOSIS OF EARLY NERVOUS DISEASE.*

By Marjorie A. Blandy, M.B., B.S.,
M.R.C.P. Lond.,
ASSISTANT PHYSICIAN, ELIZABETH GARRETT ANDERSON HOSPITAL.

It is the common experience of neurologists that the first manifestations of disease of the nervous system are not sufficiently recognised by practitioners. It is not essential for the practitioner to be an expert in the differential diagnosis of organic nervous disease, but he should be able to recognise its presence. In neurology perhaps more than in any other branch of medicine is a careful case-history of paramount importance, and the so-called negative symptoms may be especially important. Diagnosis can frequently be made on the history alone; indeed, frequently has to be made on the history alone, for example, in cases of epilepsy and some cases of the post-encephalitic syndromes. It is often found by neurologists that some early but important symptom has been omitted by the patient in giving his history, because he thought it so slight and so transient as to be of no significance. Hence leading questions must be asked, such as whether there has ever been transient double vision, weakness of a limb, or even so impressive a symptom as temporary blindness. Unfortunately this belief in the triviality of such symptoms is sometimes shared by the medical attendant. Sometimes, however, a history may be perversely misleading though entirely accurate; for instance, the symptoms of cervical rib, a congenital abnormality, may appear at any age, generally following a change of occupation to one of increasing strenuousness and entailing pulling on the arms. A short while ago I had as patient a woman of 45 who had come down in the world and who only developed the symptoms of cervical rib after going to work in a boarding-house, where she had to carry heavy trays and pails up and down stairs.

It is not enough to look for a symptom or sign with a name, such as Romberg's sign or Babinski, or even to be satisfied with the presence or absence of the knee-jerk, but it is essential to be on the look out for deviations from the normal, or differences in the responses of the two sides of the body in one individual. The type of knee-jerk is of as much importance as its exaggeration or diminution. In early paralysis agitans the diagnosis of "nervous breakdown" is frequent in the absence of alteration in the reflexes, lack of tremor, and the characteristic rigidity. These cases may be labelled hysteria because of their slowness, their awkward movements, and the uselessness of their limbs. Similarly slight ataxia in early cerebellar disease may be considered functional in the absence of marked organic signs.

Psychological Changes.

The first sign of disease of the nervous system may be a psychological one—a change of disposition noticed by the patient's friends, and sometimes even apparent to the patient himself, but beyond his control. Such an alteration in character may occur in intracranial tumour, cerebrovascular disease, disseminated sclerosis, encephalitis lethargica, neuro-syphilis, and to some extent in severe cases of subacute combined sclerosis. In intracranial tumours there may be change in temperament preceding the onset of any physical sign, and certainly occurring before the patient seeks medical advice.

During the six years I recently spent as R.M.O. and Registrar at the National Hospital for the Paralysed and Epileptic, Queen-square, I was increasingly impressed by the localising value of the type of temperament displayed by patients suffering from tumours of the cerebrum; each type being characteristic of a certain locality.

Patients with extensive *frontal tumours*, and especially with left-sided ones, are slow and dull. If the corpus callosum is involved they tend to be curiously apathetic and vegetative. For example, Miss C., a doctor's sister, had been sent to a convalescent home by the sea for a year before admission with the diagnosis of neurasthenia, because, 18 months previously, she had had a few fits, following which she had become dull, had lost interest in what had usually interested her, and had lost all initiative. Only when vision began to fail, vomiting accompanied her headaches, and weakness of one side of the body began to develop did the nature of her trouble suggest itself to her brother. She had a large glioma of the left frontal lobe involving the corpus callosum. If the tumour be smaller, leaving intact a good proportion of frontal tissue, but quickly growing and hence irritating the surrounding frontal substance, the patient shows periods of excitability with great physical restlessness. He is quick to resent and to exaggerate fancied slights, such resentment amounting at times to delusions of persecution. These patients have to be approached with the greatest tact and self-control if they are to submit to examination. Time must be spent in gaining their confidence, they must be continually humoured, and each step of the examination has to be explained to them beforehand. If not they may resist, even with violence. I remember one man who collected his dinner plates and threw them at the nurse who, he fancied, had been inattentive. These patients are filled with suspicions. They are, however, jocose and facetious and inclined to make heavy jokes at which it is wise to be amused. They may be the life and soul of the ward. Oppenheim gave the name "Witzelsucht" to this symptom. Sometimes their jokes are quite good. A woman I saw at hospital, who had, incidentally, been allowed to go blind before seeking medical advice, remarked, on hearing the visiting physician mention the number of diopters of swelling of her discs, "My husband will be amused; fancy plus-fours in my eye." Another woman, who, with frontal lobe intact had been a shy retiring creature, was enabled through the presence of a tumour in that region to attempt coquetry with a member of the staff on his ward round.

---

* A paper read at a meeting of the London Association of the Medical Women's Federation on Dec. 8th, 1925.

Patients with *temporo-sphenoidal* tumours, on the other hand, are facile, pleasant people, remaining undisturbed by alarming symptoms, such as dimness of vision, and soon forgetting each headache. They are incapable of taking very seriously the gravity of their condition. They are friendly, easy of approach, and amused by the examination, but seem lacking in depth of character. They are quietly behaved and free of spontaneous humour and facetiæ, nor are they physically restless.

It is obvious that temperamental changes, occurring early as they do, and in persons hitherto normal, are of significance, and in addition of definite localising value, especially where the physical signs are ill-marked. In *cerebral-vascular degeneration* psychological changes commonly occur in later life, producing the symptoms classed under the head of senility; but frequently the sufferer's age hardly entitles them to be classed among the aged. Local thromboses causing at the time temporary paralyses or aphasias may clear up, leaving some striking alteration in disposition or loss of recently acquired accomplishment. An instance is a male patient who had been a schoolmaster and lay preacher. This man, after recovery from a slight stroke, entirely lost his religion, to his wife's deep distress. I also remember a woman linguist who on recovery was unable to speak a word of French, in which language she had previously been proficient.

The smiling euphoria of *disseminated sclerosis* is almost pathognomonic. Once seen it is unmistakable and typical of that disease. There are depressed people among sufferers from disseminated sclerosis, but these are rare. The more hopelessly paralysed and incontinent these patients get, the more cheerful and patient they seem to become. This euphoria is an early, common one, and it may be said a merciful symptom. Actual psychoses do, very occasionally, occur in disseminated sclerosis, as the result of a plaque in the cerebral cortex. I have myself seen one such case—a girl in the early twenties with delusional depressive insanity of recent origin coupled with the typical signs of this disease.

In children, psychological changes following upon *encephalitis lethargica* are fairly common. The mental changes may be so characteristic as to leave no doubt as to the diagnosis; and yet all history of the actual attack itself may be lacking. The psychic changes may or may not be accompanied by neurological findings, nor is there any correlation between the severity of the mental disturbances and the physical signs. Indeed, as a rule, those cases showing most disturbance of conduct have the fewest physical signs. In two such cases published recently in America by B. I. Beverly and Mandel Sherman the interval between the appearance of the psychical change and of the onset of a Parkinsonian syndrome was in one case six months, and in the other two years. Both these children were referred by the juvenile court on account of disobedience, lying, fighting, stealing, and cruelty to children and animals; they were said to be entirely uncontrollable. One boy had a history of an illness three years previously during which he slept a good deal; the history of the second was entirely negative. In F. C. Shrubsall's cases of L.C.C. school children, the changes in conduct ranged from diminished power of attention at school to mental deficiency or to loss of moral sense. In a case of the latter quoted, three years after the attack, a girl of 10 took suddenly to lying, stealing, spitefulness, and wanting her own way in everything. In this case and in many others the intelligence tests showed no lowering of the intellectual level.

Uncontrollable outbursts of involuntary laughing or crying may be a symptom of organic brain disease before the physical signs of any cerebral lesion become manifest. Féré reports the case of an elderly man of 64 who used to become convulsed with laughter over trifles and was entirely unable to control the performance. A few months later this was followed by first a right and then a left hemiplegia. Patients with cerebral arteriosclerosis causing diffused patches of softening especially in the basal regions of the brain, likewise often show signs of an abnormal emotional state, which is undoubtedly the direct outcome of the disease. In these cases as a rule the stimuli are often inadequate and inappropriate, and the outbursts are irrelevant to the feelings of the patients. The patients are aware of this and resent their helplessness to control themselves, and it often leads to misunderstandings. Dr. S. A. Kinnier Wilson tells the story of a man with this affliction. He lost his heart to the ward maid; when her father demanded his intentions he burst out laughing.

Cerebral syphilis may often be ushered in by an acute psychosis with delusions and hallucinations.

Occasionally *subacute combined degeneration of the cord*, if running a very rapid course, is accompanied by mental symptoms, confusion, depression. I saw a case of this nature recently which had been provisionally regarded as functional, owing to her mental confusion accompanied by somewhat indefinite signs. The disease developed rapidly, however, and when I examined her she showed the typical signs, with jaundice. Three weeks later the findings were confirmed at autopsy.

Objective Appearances.

Quick appreciation of the outward details of a patient's appearance and manner is essential to the neurologist, since the diseases with which he has to deal are usually much more objective than diseases of other systems of the body. An accurate diagnosis is often revealed at a glance to the trained eye, and only confirmed or perhaps modified by the detailed physical examination which follows. A waitress was dismissed from her employment for becoming slow, her leisurely movements exasperating her employer. This poor woman had had an attack of so-called influenza six months before. On being questioned she admitted having had double vision at the time, but had thought nothing of it. What brought her to hospital was the recent onset of involuntary tremors in the right hand. In appearance she was an obvious case of post-encephalitic Parkinsonian syndrome, of hemiplegic distribution. Examination confirmed this diagnosis, and the slowness of gait and action that her employer complained of was due to the muscular rigidity consequent upon this disease.

Frequently after an attack of encephalitis lethargica the first thing that obtrudes itself into the patient's consciousness is that she is getting slow; slow in walking, slow in performing any customary act, and she is slow also in attributing her condition to any possible illness. A milder attack of the disease may leave even less trace. A detailed history and minute observation of very slight changes in muscle tone, in gait, in the lines and mobility of facial expression, may decide the diagnosis and save the patient from being labelled functional. In the absence of any indicative history in a middle-aged person such findings would suggest the idiopathic type of paralysis agitans.

Other objective signs of which the patient is unaware are weakness of the emotional movements of one side of the face, while the voluntary contraction remains unaffected. This is usually an early sign in tumours of the temporal lobe, is of great localising value, and is most apparent when the patient is chatting. The commencing enlargement of the nose, and bones of the jaw, and of the extremities in pituitary hypersecretion is obvious to the observer, though insidious enough to be unnoticed by the patient or his friends.

J. P. Martin points out that luxuriant iron-grey hair without trace of baldness in a man of middle age, the subject of some nervous lesion, suggests neurosyphilis. A glance should note myosis, inequality of pupils; the toxic colour and lack of expression together with the slightly inquiring eyebrows of the tabetic. This lack of expression, due to loss of tone in the facial muscles, is quite characteristic and cannot be confounded with that of the Parkinsonian, in whom it arises from hypertonus and loss of mobility.

Subjective Symptoms.

Subjective symptoms are very important in early nervous disease. These sensations frequently precede the appearance of a paresis or sensory loss, and may be misconstrued. When one thinks of the intricacies of motor coördination that are performed by means of the pyramidal tract, for instance, it is clear that clinical tests can only disclose crude defects. The first sign of the impairment of some skilled acquired movement can be apparent to the patient alone. A man with a slow-growing endothelioma of the left frontal and rolandic areas was aware that his writing had deteriorated, whereas at the time the physical examination was negative. In F. M. R. Walshe's series of cases of polyneuritis following upon diphtheritic infection of wounds, the patients in many cases were already aware of fatigue of the legs and aching of the calf muscles on exertion with painful cramps at night, when clinically only tenderness of these muscles could be found. Such symptoms may precede by weeks the disappearance of the tendon-jerks; indeed, the latter undergo a preliminary exaltation. In cases of polyneuritis and frequently in tabes and subacute combined, the ankle-jerks disappear before the knee-jerks. I would therefore emphasise the desirability of adding the ankle-jerk to the routine neurological examination of any case. I would also like to interpolate here a plea for more precision on the part of the medical profession in general in the use of the term "neuritis." Any vague and intractable pain is called neuritis, usually as a cloak of ignorance and a placebo to the patient, who is immediately proud to think she is suffering from something so high-sounding and at the same time she knows, from the discussions of her friends, that she need not expect a rapid cure. Fibrositis is a longer word, can be uttered with due significance, and is at least more likely to be accurate. The term "neuritis" should be reserved for interstitial neuritis, such as brachial neuritis, sciatica, &c. Diphtheritic polyneuritis would be more correctly termed "neuronitis" as the whole neurone including its spinal cord termination is involved.

Pain.—When patients complain of pain, the nature of the pain, its duration, and its localisation is important. Farquhar Buzzard maintains that an accurate description of lightning pains is diagnostic. He says the pains are a sharp stab at right angles to the limb in which they occur, and they may be present for months or years before the onset of any of the physical signs of tabes. In spinal tumours again the nature of the pain felt is suggestive of the diagnosis. There is almost invariably a definite thermal element in addition to the constricting element; that is, they feel a band round the affected part which is "burning hot," usually, sometimes cold, or both hot and cold. Fixed intractable pains of central spinal origin occur in disseminated sclerosis, in syringomyelia, and in other cord lesions. It is necessary to differentiate pain from an organic source from sensations of neurasthenic origin. These latter are usually described as pains, but questioning will elicit that they are rather unpleasant sensations than true pains.

Headache is an early symptom in many nervous diseases. Persistent severe headache, unyielding to treatment, in a young adult should suggest syphilis as the cause. A man who had been treated symptomatically for headache when young at the National Hospital returned ten years later a well-marked case of tabes. True headache must be differentiated by the history from neuralgia, and the cephalic sensations so common in neurasthenia and psychasthenia, and in women at the menopause. The "headache" in these cases proves to be not painful at all, but is a feeling of pressure, of fullness, a weight or a band round the head, &c. It is present on waking and improves as the day draws on, the reverse of what happens in the organic type. However, true paroxysmal headaches of a migrainous nature frequently do occur in women for the first time at the menopause. They may be accompanied by vomiting and coincide with the period of menstruation, and are probably due to a compensatory hyperplasia of the pituitary. In many of these cases the sella turcica is partially bridged over, which may interfere with the enlarging of the gland and so cause the symptoms.

Migraine should, of course, give rise to no confusion.

Sleep is frequently disturbed at the onset of many nervous illnesses. The man suffering from cerebral syphilis is drowsy by day, but mildly delirious by night. The man with a pituitary tumour yawns in your face, or falls asleep during your examination. Even those interesting cases of narcolepsy have almost certainly an organic basis. In these cases the pituitary fossa is abnormally small. A girl in the twenties complained that she was always falling asleep, but more especially when she laughed would sleep suddenly overcome her. She would "dog-nap," as she called it, over her work, and once she laughed when cycling, and immediately fell both asleep and off.

In the acute stages of encephalitis lethargica the patients may be almost impossible to rouse, or they may suffer from sleeplessness and restlessness by night, attaining in some instances to the wildest maniacal delirium.

Fits may be the first intimation of organic nervous disease of the brain. They occur as a first symptom in a definite number of cases of disseminated sclerosis when there is cortical or subcortical involvement. I have now a patient suffering from disseminated sclerosis who was quite well until she had a fit 11 years ago. After the fit she had diplopia and weakness of one limb, both of which cleared up. The diagnosis at that time was "nervous breakdown." I have seen several other cases of disseminated sclerosis who have had fits from time to time throughout the course of their disease. More frequently fits occur as an early symptom in intracranial tumour, and may precede the physical signs of tumour for many years. One boy had fits, apparently of a generalised epileptic nature, since the age of 15 years. These generalised fits became gradually interspersed with local seizures until these formed the majority and he rarely lost consciousness. He still had no physical signs that might not be attributed to the frequency of the fits, nor had he any papillœdema until just before he was operated on at the age of 25, when a huge endothelioma weighing about 200 g. was removed from his right frontal area. That interesting type of seizure, the temporo-sphenoidal fit, may occur in both idiopathic epilepsy and in organic intracranial lesions of this region, and in the case of tumours the attacks may precede by months the onset of any physical sign of tumour. These attacks are liable to be considered purely of psychological origin, so that a brief description of them here may not be out of place. The attacks consist of an olfactory aura, sometimes attended by a gustatory aura and followed by what is known as the dreamy state. The smell is usually nauseous, resembling that of burning feathers or organic matter, more rarely it is pleasant. In one case removal of a tumour resulted in the change of a pleasant to an unpleasant smell. I think the following description in the patient's own words is better than anything I can say. (The rather unusual style of the language is due to his being a Dane.) "I get a sort of feeling like a taste in my mouth. It is not exactly nasty, but it is not nice. I have a smell at the same time of similar nature. I then get a sensation as if I were living in a second or third world of life, when this other life happens I know it. I want to remember the occurrences in between (i.e., when normal), but I cannot. I usually hear a melody to start with; I know the melody at the time, but I cannot remember it afterwards. I often hear voices, men's and women's voices, who are not behaving haphazard; there is some point and sequence in what they are doing and saying. And I remember an old voice scolding and a little child's voice. I can see the people, and I know whether they are sympathetic or antipathetic to each other, and I know who they are during the attack, but after I cannot recollect."

Disturbances of Vision.

Sudden unilateral blindness is commonly a first sign of disseminated sclerosis. It may precede the general attack by as long as 20 years or more, but is often not mentioned unless inquired for. Again, a history of blindness may be given when what has actually occurred has been a complete ptosis. These patients seem unable to realise that they can still see. The ptosis may occur in hysteria, when it is usually bilateral, in neoplasm of the skull or brain, in syphilis, myasthenia gravis, and at the onset of encephalitis lethargica. A history of diplopia is highly significant. It is an early symptom in a large number of organic nervous diseases, and is comparatively rare in hysteria, where if there be multiplicity of vision it is more commonly a polyopia. The patient is conscious of diplopia when the causal ocular palsy is so slight as to be almost or quite impossible to detect by the gross methods at our service.

Conclusion.

I would like, in conclusion, to protest against that terminological abomination in diagnosis the "nervous breakdown." What is a nervous breakdown? In my personal experience among diseases thus diagnosed have been intracranial tumour, disseminated sclerosis, encephalitis lethargica, cerebral syphilis and neurisyphilis, paraplegia, cerebrovascular disease, psychosis, hysteria with or without paralyses, neurasthenia. What happens when nerves break down is Wallerian degeneration; but this physiological fact does not appear to be in the mind of the physician who makes this facile and meaningless diagnosis.

Two positive suggestions I would make are (1) that ophthalmoscopic examination of the fundus oculi should be part of the routine examination of every patient; (2) that lumbar punctures should be done in cases of suspected nervous disease. A properly carried out qualitative and cytological examination, including the Wassermann reaction, yields information upon which the diagnosis of the nature of the disease often rests and negative findings are of an almost equal value.

Two Lectures
ON THE
EFFICIENCY OF THE HEART AND ITS MEASUREMENT.

University of London Advanced Lectures in Physiology, delivered at University College, Nov. 30th and Dec. 1st, 1925,

By YANDELL HENDERSON,
PROFESSOR OF APPLIED PHYSIOLOGY, YALE UNIVERSITY.

Lecture II.*—Applications and Results on Man.

The problem which we are considering is essentially that upon which the greatest of English physiologists made his supreme contribution. In this city (London) in the year 1628 William Harvey published the discovery of the circulation of the blood. Harvey solved the problem qualitatively. It is only now, 300 years later, that physiology has achieved its quantitative solution—the volume of blood that the heart pumps in a minute.

With the general problem now solved, the next step must be the application of measurements of the circulation to physiological study and clinical use. But it is only against a background of the principles of respiratory metabolism, and the mechanical conditions of the circulation, as set forth in the preceding lecture, that we can properly appreciate the significance of the data that are now becoming available from investigations on man himself, the best of all subjects for physiological study.

Failure of Physical Methods.

All mechanical methods of measuring the volume of the circulation have failed. When we learned, about 20 years ago, to measure arterial pressure on man, it was thought that perhaps the amplitude of the pulse—that is, the pulse pressure—would be proportional to the stroke volume of the heart. If so, the product of the pulse pressure and the pulse-rate for different times and conditions would indicate the relative volume of the circulation. But the elasticity and capacity of the arterial system are too variable for any reliance to be placed on this method.

Another line which I tried to develop depends on the recoil of the entire body under the impulse imparted to it by the discharge of blood from the heart at each beat. This device would be analogous to determining the weight and velocity of a cannon ball by measuring the extent to which the cannon recoils when the ball is fired out of it. You may see the principle the next time you weigh yourself on a spring balance. After you have dropped your penny in the slot, stand quite still and, if the machine is delicately adjusted, you will see the pointer over the dial vibrating with each stroke of the heart. If you have been exercising it will vibrate more widely. But no very practical results have as yet developed.

Success of Method Based on Metabolism.

For the beginning of a real solution of the problem we are indebted to the physiologist Fick. Some 40 or 50 years ago he laid down the principle upon which the greater part of what was said in my first lecture is based. It is that we can calculate the circulation from a determination of the amount of oxygen a man or animal is consuming a minute, and from analyses of the gases contained in the arterial blood and in venous blood from the right heart. The oxygen consumption of the body divided by the arterio-venous oxygen difference gives a quotient which is the volume of the circulation. Thus, for example, if the arterio-venous oxygen difference is 5 volumes per cent. and the volume of oxygen absorbed in a minute is 500 c.cm., the volume of the circulation must be 10,000 c.cm. or 10 litres, because 500 c.cm. is 5 per cent. of 10 litres, that is, $500/0{\cdot}05 = 10{,}000$. The same simple calculation can be applied in order to measure the circulation on the basis of the volume of carbon dioxide exhaled and the arterio-venous carbon dioxide difference.

Zuntz and Hagemann,[1] in their classical investigations on the metabolism and energetics of the horse, first tried to put this principle into practice. Much of the procedure was then new and complicated, and it is not surprising that their results were not very concordant one with another. It is amusing to recall a controversy between Zuntz and Bohr over the results, a controversy which still has a certain significance. Bohr believed that a considerable amount of combustion, at least during muscular work, occurs in the lungs. He argued that the volume of the circulation found by Zuntz would be insufficient to transport to the tissues the oxygen consumed by the animal. If oxygen were consumed in the lungs the Fick principle would not be valid. Conversely, if the circulation is actually smaller during hard work than the Fick procedure shows it, then oxygen is consumed in the lungs, as Bohr believed. In reality, as nearly as we can now figure from the results obtained by Zuntz and Hagemann, although the arterio-venous oxygen differences during rest were certainly much too high, the stroke index of a horse amounts to about 2 c.cm. per kilo per beat—a figure quite close to that which we now know to be correct for all vigorous mammals, large and small.

In the 27 years since Zuntz demonstrated the feasibility of the Fick principle great technical advances have been made, so that analyses which were then difficult and inaccurate are now comparatively easy and exact. We have learnt better how to determine the respiratory gaseous exchange on men and animals; and many investigators can now insert a needle into an artery even of a man and can draw a sample of arterial blood for analysis. From animals it is a simple, painless, and generally harmless operation to draw blood directly from the right heart also by means of a hypodermic syringe inserted through the body wall. As regards the results from animals obtained by many investigators recently, it suffices to say that during rest, probably not very complete rest, the arterio-venous oxygen difference found is usually 4 or 5 volumes per cent. and sometimes as low as 3 volumes per cent. Such figures combined with the oxygen consumption and the body-weights of the subjects (dogs) calculate out to stroke indices of about 1·3 to 1·8 c.cm. per kilo per beat. These figures are for the normal, unanæsthetised, unoperated, healthy animal. But as a rule, under anæsthesia, and especially under operation or experiment, the stroke volume and circulation are decreased far below normal. The arterio-venous oxygen difference rises, therefore, far above normal. Such a depression of the circulation gradually develops towards tissue asphyxia and death.

Application of the Fick Principle on Man.

On man cardiac puncture is not done, and even the withdrawal of blood from an artery is often a rather troublesome operation. Accordingly, much time and effort have been devoted by many investigators in recent years to developing what we may call respiratory procedures to afford similar data. An essential step was the discovery by Haldane and Priestley in 1905 that by making a sudden very deep expiration through a tube we can obtain in the tube, and can draw off for use, a sample of air from the depths of the lungs; and that this alveolar air is in gaseous equilibrium with the arterial blood. Plesch (1909) gave us the first indication as to how we may obtain air from the lungs which would be virtually in gaseous equilibrium with the venous blood.

---

* Lecture I. appeared in the last issue of The Lancet.

[1] For references to literature see note at the end of this lecture.

The simplest procedure developed from this idea is to put into a rubber bag 2 or 3 litres of air, or much better oxygen, containing an amount of carbon dioxide between 5 and 6 per cent. After an initial deep expiration to empty the lungs as far as possible, the contents of the bag are inhaled and blown back into the bag three or four times in 10 seconds. The gas mixture is analysed for its percentage of carbon dioxide; then it is again inhaled for 20 seconds this time and analysed; and again inhaled for 30 seconds and analysed. If these three analyses show the same percentage of carbon dioxide, this agreement indicates that the amount of carbon dioxide in the bag is in equilibrium with that in the venous blood coming to the lungs, after that blood is fully oxygenated, but without at the same time either gaining or losing carbon dioxide.

Such air we call "virtual venous pulmonary air," and the difference between the pressure of carbon dioxide in it and that in "arterial pulmonary air" obtained by the procedure of Haldane and Priestley, gives the datum that we need. It is usually a little more than 1 per cent. of an atmosphere for a normal man at rest. In order to put this quantity into terms of volumes per cent. of arterio-venous difference we must multiply it by a factor for the capacity of the blood to absorb carbon dioxide. This factor is the amount of carbon dioxide that blood will take up and give off for each change of 1 mm. of pressure, or 1 per cent. of an atmosphere, of carbon dioxide. It is obtained from the well-known carbon dioxide dissociation curve of Christiansen, Douglas, and Haldane, and is 0·4 volumes per cent. for 1 mm., or 2·88 volumes per cent. for 1 per cent. of an atmosphere difference of pressure.

There are now available many observations by different investigators by means of methods of this general character. Some have employed more elaborate measures yielding venous pulmonary airs equilibrated in respect both to oxygen and carbon dioxide. Douglas and Haldane measured the circulation in this way on normal men and found in some vigorous persons that the stroke volume during rest is so large that, even up to a metabolism of ten times the basal rate, the oxygen requirements may be met wholly by the increased rapidity of the pulse and the increased percentage utilisation of oxygen from the blood. During exercise their data indicated that the stroke volume in Douglas was not appreciably increased. Both during rest and work his stroke index was 1·9 c.cm. His resting arterio-venous oxygen difference was only 3·2 volumes per cent., thus affording a very large reserve in the oxygen capacity of the blood.

The Stroke Volume of the Heart in Man.

If this is an accurate indication of the circulation in some vigorous persons, the behaviour of the heart is in accord with a theory which I advanced nearly 20 years ago covering two points: (1) that the stroke volume of the heart during rest is much larger, and the arterio-venous oxygen difference therefore much smaller, than had previously been supposed; and (2) that the stroke volume for all normal heart-rates for any vigorous individual during rest and exercise is a uniform or only slightly varying quantity. These propositions were based on observations and measurements of the volume curves of the hearts of dogs. As shown in Fig. 2 of the preceding lecture, the strokes have an amplitude of about 2 c.cm. per kilo of animal and have a sufficient interval of diastasis (the pause between beats) at slow pulse-rates, so that by an abbreviation of diastasis at more rapid rates a sufficient number of beats of unvarying size could be obtained to afford the largest circulation (as I then thought) needed during vigorous muscular exertion.

The first part of this theory has now been fully confirmed by observations on man, not only those of Douglas and Haldane, but also by similar and somewhat simpler methods by Meakins and Davies, by Henderson and Prince, by Barcroft, Roughton, and Shoji, by Robinson and Burwell, by Bock and his associates, and by a number of others. Thus we now know with a high degree of certainty and precision that the arterio-venous oxygen difference may be even below 4 volumes per cent. in a vigorous person during bodily rest. The stroke index during rest must therefore be 1·5 c.cm. per kilo per beat or more.

Until a few years ago the evidence available indicated that the arterio-venous oxygen difference was of the magnitude of 6 or 7 volumes per cent. From such figures, with those for the basal oxygen consumption at 250 c.cm. per minute, the conclusion followed by simple arithmetic that the circulation was only 3·5 to 4 litres a minute. A circulation of this volume with a pulse-rate of 70 a minute would make the stroke volume of the heart of a man at rest only 50 or 60 c.cm., a stroke index of only about 0·7. When the size of stroke was then calculated for the 10- or 15-fold increase of oxygen consumption during hard work, no conclusion was possible for Zuntz and the other investigators of those days, except that the strokes of the heart are several times as large during exercise as in rest.

We now know that the arterio-venous oxygen difference in a vigorous man or animal is only half as large, and therefore that the circulation during rest is twice as large, as they then supposed. For vigorous exercise we can figure that an athlete of 60 kilos consuming 3 litres of oxygen a minute, with his heart beating 180 times a minute, would just balance his oxygen account if his stroke volume were 100 c.cm. and his circulation, therefore, 18 litres. But there would then be very little oxygen left in his venous blood, less than 2 volumes per cent. The arterio-venous oxygen difference would be more than 16. If in such a man each stroke of the heart during exercise discharged the same volume as during bodily rest, that is the way the factors would balance.

Man is a very vigorous animal, and his vigour is largely based upon the factors of safety, or reserves, afforded by a low arterio-venous oxygen difference during rest and a correspondingly large stroke volume. It is wholly unnecessary and contrary to fact for such an organism, or mechanism, to have to increase the stroke volume 400 or 500 per cent. during muscular exercise as everyone believed only a few years ago. It seems probable that during all moderate activities about one's room or office or laboratory, with pulse-rates from 60 to 80 or 90, or possibly a little more, the circulation in vigorous individuals varies in proportion to the pulse-rate, and that the stroke volume of the heart is not appreciably increased. During more vigorous muscular work, however, I have come to doubt that this uniformity of stroke volume is maintained, and to regard it as probable that at a pulse-rate of 150 beats per minute, or 180 during an athletic contest, the stroke index may be increased to as much as 3 c.cm. per kilo per beat, or about double the stroke volume during rest. But it was only when a better method became available that this point was established.

On the whole, the results that have been derived from the application of the Fick principle to man are clear and important. But the method is really one solely for the laboratory, for research and instruction purposes. It requires special precautions and the coöperation of a trained subject; and even then the error of the method is 10 to 20 per cent. It becomes quite unreliable as soon as, owing to muscular activity or disease, the capacity of the blood to absorb and transport gases is altered.

The Nitrous Oxide Method.

Accordingly, Krogh and Lindhard attempted some years ago to develop a method based on the rate at which nitrous oxide is absorbed into the blood, when it is inhaled with air somewhat as in the procedure of Plesch above described. This method, in the form in which its inventors describe and use it, is not only more difficult, but far less accurate than the application of the Fick principle. Many other investigators have tried to use the method of Krogh and Lindhard, but all have given it up. Its results are often widely discordant, not only with the now known volume of the circulation, but also with each other. In successive determinations on the same subject under uniform conditions, the results are often twice as large in one as in the next, instead of nearly identical as they should be. Krogh and Lindhard regard these variations as indicating the variable volume of the circulation, but they are in reality errors inherent in the method. It was considered by Krogh and Lindhard to be necessary that the whole procedure or inhaling and exhaling the gas mixture should be completed in a time (30 or 40 seconds) less than that in which some of the blood makes the round of the circulation and returns to the lungs again. They argued that after this period, not only would nitrous oxide be going into the arterial blood from the air in the lungs, but some of the gas would be returning to the lungs in the venous blood. In fact, however, so brief a period renders it impossible to attain complete mixture of the inhaled gas with the air in the lungs and accurate determinations of the concentrations of the gas at the beginning and end of the period.

In spite of the failure of their method, physiology is greatly indebted to Krogh and Lindhard for this first gallant attempt to use a foreign gas as the means of measuring the circulation. To a certain extent my own recent investigations take their origin from it; for noting its defects I determined to use much longer periods of inhalation, to use a gas which could be more easily analysed, and to try to work out a correction (which has by good fortune proved unnecessary) for the amount brought back to the lungs by the venous blood.

PRINCIPLES CONTROLLING THE ABSORPTION OF GASES.

Consequently, I have now to describe a method, recently developed by my associate Dr. H. W. Haggard and myself, which seems, on the basis of the rather extensive data already available, to afford a simple, accurate, and almost universally applicable solution of the problem of measuring the circulation in man. For more than 20 years I have been searching for such a method. I had reached the point that I never expected to find it, and an equally fixed determination never to cease searching. The discovery was the result of a bit of good luck happening in the course of a systematic search.

In my laboratory we have been for some years past studying the action on man of all the varieties of gases and vapours which occur in modern industry, and which we all inhale (from motor-cars, coal smoke, illuminating gas, &c.) to some extent. Haggard had also made a very thorough study of the absorption and elimination of ethyl ether in connexion with anæsthesia. Out of these studies we had developed certain principles governing the absorption and elimination of volatile substances through the lungs, and particularly some mathematical formulæ, from which a number of important considerations became evident. All of the considerations thus derived proved on experimental test to be sound and practical. I have discussed them and have given the formulæ quite fully in some lectures [2] on anæsthesia and related matters recently. So only a few of the formulæ need be repeated now. The quantities considered and their symbols are as follows:—

(L) Effective pulmonary ventilation in litres per minute, that is, respiration minus the volume of air which merely enters the dead space.

(C) Concentration of the gas in milligrammes per litre of inspired air, when warmed to body temperature and saturated with moisture, as it is in the lungs.

(K) Coefficient of distribution of the gas between equal volumes of lung air and pulmonary blood.

(G) Litres or kilos of blood in active circulation in the body. In other words, the effective blood volume at the time.

(B) Circulation, defined as the number of litres or kilos of blood flowing through the lungs in one minute.

(W) Body-weight in kilos.

By combining these quantities we obtain the following formulæ:—

(1) LC = the amount of the gas inhaled into the lungs per minute.

(2) $LC \times \frac{L}{BK + L}$ = amount of the gas again exhaled from the lungs per minute.

(3) $LC \times \frac{BK}{BK + L}$ = amount of the gas absorbed per minute into the blood, before any of the blood completes the round of the circulation and returns to the lungs from the venous side; that is, the initial rate of absorption.

(4) $\frac{LCK}{BK + L}$ = amount of gas in milligrammes absorbed per litre of blood flowing through the lungs.

(5) $\frac{LCKG}{BK + L}$ = amount of gas absorbed during the first complete circulation of the blood, which is accomplished in the time $\frac{G}{B}$, a period less than one minute even during bodily rest.

(6) $\frac{LCKG}{BK + L} \times \frac{G}{W}$ = the amount of the gas brought back to the lungs by the venous blood during the second round of the circulation.

In these formulæ, the solubility of the gas in the blood (usually nearly the same as its solubility in water and expressed by K) exercises a dominating influence. If we examine this influence as revealed in the formulæ, we find that the rate at which a quite soluble gas (with a high value of K) is absorbed into the body, is determined to a very large extent by the volume of breathing (L), and to a very small extent by the circulation (B). Gases and vapours of a high solubility are therefore quite unsuited to use for measuring the circulation. On the other hand, with gases and vapours for which the coefficient of solubility (K) is small, the rate of absorption from the air of the lungs into the blood is little affected by variations in breathing (L), but depends almost wholly on the blood flow through the lungs. With this principle to guide us, we undertook to make a systematic test of all organic gases and vapours of low solubility. This search might have kept us busy for years but for the chance which led us early to try the vapour of ethyl iodide.

THE ETHYL IODIDE METHOD OF MEASURING THE CIRCULATION.

Ethyl iodide is a liquid with an odour somewhat like chloroform. It is as volatile as alcohol; and the vapour, as we have determined, has a solubility, or coefficient of distribution between air and blood in the lungs, which is expressed by 2; that is, when the alveolar air contains a certain number of milligrammes, or fraction of a milligramme, per litre, the blood flowing from the lungs always contains twice this amount per litre.

Ethyl iodide vapour, even when only minute amounts are contained in the air, can be determined, as we have found, with ease and accuracy by the use of iodine pentoxide to liberate iodine. Determination of the amount of this iodine by titration with thiosulphate is one of the most accurate methods of analysis that chemistry affords. The vapour of ethyl iodide mixed with the inspired air is so dilute that an experiment involves the absorption into the body of an amount of iodine corresponding to only about 0·2 g. of sodium iodide. Most important of all is the fact, as we were fortunate enough to discover, that ethyl iodide is decomposed in the tissues, presumably into sodium iodide and alcohol. The amount of ethyl iodide returned to the lungs in the venous blood is therefore so small that no correction seems necessary on this account even when periods of inhalation of 10 to 20 minutes are used.

A few drops of liquid ethyl iodide are vaporised in about 100 litres of air, or correspondingly more for experiments on exercise and large volumes of breathing, in a large spirometer. The subject inhales this vapour and air through a rubber tube, mouthpiece, and valves, and the expired air passes through a mixing chamber. The technique is essentially like that for the determination of the basal metabolism. It is convenient to combine the two determinations. By a device attached to the mouthpiece, a sample of alveolar air is automatically collected. This sample and equal volumes of the inspired and expired air are analysed iodometrically as above indicated and the circulation is calculated by a simple arithmetical formula—viz., the volume of air breathed per minute (as measured on the spirometer) is multiplied by the difference in the amount of ethyl iodide in the inspired and expired air, and is divided by twice the amount found in the alveolar air. A complete determination takes 30 or 40 minutes, including the calculations. It requires no training or coöperation on the part of the subject. It is a method which seems to be as well suited to the clinic as to the laboratory. It has been subjected to every test and control that we could devise, both on men and on animals, to test its accuracy. Perhaps the best test of all is the concordance of results obtained by this method with each other. In successive tests on the same individual under the same conditions closely agreeing measurements are obtained.

---

[2] To be published in the British Medical Journal and in the annual volume of the Dental Board of the United Kingdom.

SUMMARY OF RESULTS OBTAINED WITH THE ETHYL IODIDE METHOD.

Many data have already been collected by this method and more are accumulating rapidly. The persons examined range from athletes to patients with well-marked heart disease. The general aspects of the results obtained have been indicated already in the course of these lectures. Thus physical vigour is found to be correlated with a large capacity in the circulation to transport oxygen even during bodily rest and consequently by a low arterio-venous oxygen difference. The athlete in complete rest has a circulation so large in relation to his oxygen consumption that his venous blood contains only a few volumes per cent. less oxygen than the arterial. At the other end of the scale it is found that even the ambulant cardiac patient has a circulation so much slower than normal that the difference in the oxygen content of the arterial and venous blood, even during rest, may amount to 6 or 7 volumes per cent. He has about the volume of circulation that we used, not many years ago, to assume in healthy people.

The athlete is characterised by a heart which during bodily rest makes large beats at a slow rhythm. Thus his stroke index is 1·5 c.cm. or more per kilo per beat. With moderate activity there appears to be little increase in the size of stroke. The increased blood flow is afforded chiefly by the acceleration of the pulse. With increased muscular exertion the stroke volume also increases, so that an athlete whose stroke index at rest (sitting) may be 1·5 c.cm. per kilo per beat, increases to double this volume during vigorous exertion. The total circulation, which is 5 to 7 litres per minute during rest, rises above 20 litres a minute during vigorous exercise, and may even exceed 30 litres (8 gallons) a minute in an athlete of the type that rows in a university crew and during a closely contested race. At the same time, as we have found in collateral investigations, such an athlete is doing an amount of work with his oar amounting to 0·6 horse-power. He is breathing 80 litres of air a minute and consuming between 3 and 4 litres of oxygen per minute. At such intensities of effort as these, and in fact above about 2 litres of oxygen, the reserve chiefly drawn on is the oxygen-holding capacity of the blood, so that the blood may have had more than half of its oxygen absorbed as it rushes through the tissues. When the circulation encroaches on the lower third of this reserve the athlete comes to the end of his physical power.

Observations have been made on a number of women ranging from athletic young girls up to women in middle life. During rest or moderate exertion their circulation is in every way comparable to that of men of corresponding weight, muscular development, and manner of life. For both men and women a sedentary life and overweight show their effects in a smaller stroke index of the heart and more rapid pulse even during rest. The most striking result of these investigations on the circulation in man has been the demonstration of the extraordinary difference between the volume of the circulation when the individual is lying down or standing. This difference in many persons who on every other score would be adjudged healthy may be as much as 40, and in some even 50, per cent. In comparatively few persons it is less than 20 per cent. Thus the circulation may be 8 or 9 litres a minute when the individual is at rest in bed and only 5 or 6 litres a minute after he has been standing quite still for some time. The effect of position on the circulation in animals was studied some 20 years ago by Leonard Hill, and these results on men are entirely in accord with those which he obtained on animals. It should be added that this effect on men was first observed by Bock and Field, whose work has not yet been published, but who called my attention to this important matter. It explains why rest in bed plays so great a part in recovering from fatigue. It affords the strongest evidence that in no occupation should a man, woman, or child be kept standing in one spot and still for more than a very brief period.

Finally, mention may be made of the effect of hot baths on the circulation as revealed in these investigations. As compared with rest in an ordinary temperature, a hot bath increases the volume of the circulation so much that the arterio-venous oxygen difference falls to a lower figure than under any other conditions. Thus it appears that a hot bath involves an intensive hyper-oxygenation of the tissues of the body.

CONCLUSIONS.

Now at last we know with precision the stroke volume of the heart and the volume of the circulation. We know the range of variation in normal men and women, and in general in all mammals. On the basis of such data the activity of the heart and the volume of the blood-stream are here correlated quantitatively with the size, vigour, and gaseous exchange of men and animals during rest and muscular work. The principles underlying this correlation are formulated. The volume of the blood-stream through the lungs is determined from the rate of absorption of ethyl iodide vapour. This method affords an efficient and clinically practicable means of measuring the circulation, not only in normal persons, both those of athletic and those of sedentary habit, but also in patients with moderate cardiac impairment.

Thus the problem of measuring the volume of the blood-stream—the problem which was in effect defined by William Harvey when he discovered the circulation nearly 300 years ago—is now solved.

YORKSHIRE APPEAL FOR CANCER RESEARCH.—The Yorkshire Council of the British Empire Cancer Campaign, at a recent meeting at Leeds General Infirmary, resolved to issue an appeal next month for £75,000 for research work in the county. The appeal is to follow a meeting of the Council on Jan. 18th. The hon. secretary of the Council reported that the county had been divided into 18 districts, and each district would have three or more representatives on the Council. It would probably cost about £5000 a year to run a cancer research laboratory on up-to-date lines. Sir Berkeley Moynihan said that the idea was to have a cancer research centre in Leeds, and they had every right to expect that work done there would be very fruitful. It was their desire to work in association with the University department of pathology. The University was prepared to offer substantial financial help for a limited period, and to appoint a professor as a member of the full-time University staff to be at the head of the department.

A CLINICAL STUDY OF THE DICK TEST.

BY ALEXANDER JOE, *D.S.C.*, M.D.,
D.P.H. EDIN.,
ASSISTANT MEDICAL OFFICER OF HEALTH, EDINBURGH;
LATE INTERIM MEDICAL SUPERINTENDENT,
EDINBURGH CITY HOSPITAL.

A PAPER was published in THE LANCET from the Edinburgh City Hospital in January of this year by Ker, McGarrity, and McCartney, giving details of their preliminary work with the Dick test.[1] The results obtained at that time were highly suggestive and warranted a continuation, the first essential being to try out a further series of filtrates with a view to finding a reliable toxin. I had been associated with Dr. Ker in testing with one or two of the toxins whose results were recorded in the former paper, and we continued our work with a batch of toxins, prepared as previously described by Dr. J. E. McCartney. We had experimented with five different toxins in addition to those reported on in the previous paper, when we lit on one that we thought was giving critical results, but we had only completed about 100 tests with it when I suffered the very severe reverse of the loss of my chief. Later on, however, I was able to continue the work, and this paper embodies the experience obtained in the carrying out of over 1400 Dick tests.

Variation in Results obtained with Different Filtrates.

It is obvious that the question of choice of toxin to be employed is one of the very highest importance, and a method of accurate standardisation is essential before the test can find its fullest application. The following gives some idea of the varying results obtained with different preparations, and I think it may be fairly inferred from them that the test is quantitative.

For descriptive purposes I have named the filtrates with which these comparative tests were made A and B. Toxin A was supplied me by Dr. R. A. O'Brien and is a product of an American strain of the hæmolytic streptococcus. Toxin B was made by Dr. McCartney from a strain of the organism isolated in the Edinburgh City Hospital. It wil be remembered that this toxin was obtained by growing hæmolytic streptococci isolated from scarlet fever throats in rabbit blood broth for five days, separating the organisms from the filtrate by centrifuging at high speed, and then passing it through a Berkefeld filter. The test dose in all the following experiments was 0·1 c.cm.

A series of 34 scarlet patients, whose day of illness ranged from the fourth to the twenty-ninth, were tested with different concentrations of Toxin B. In 1 in 1000 dilution there were 21 positives thrown up, whereas with 1 in 500 every one of the 34 was positive. Moreover, the negatives obtained with the 1 in 1000 dilution occurred in cases from their fifteenth day onward, with the exception of two in which negatives were obtained on the eleventh and thirteenth days.

Toxin A tried on a batch of 17 diphtheria patients in a dilution of 1 in 1000 gave 14 positives, but this was reduced to 12 when a dilution of 1 in 6000 was used. In 12 scarlet convalescents, however, each dilution showed the same number of positives—viz., 4.

It would also appear that different strains of scarlatinal hæmolytic streptococci produce toxins of varying potency. In a batch of 17 diphtheria patients mentioned above as giving 14 positives when Toxin A was used in a dilution of 1 in 1000, Toxin B in the same dilution gave only 9 positives. Also in the same series of 12 scarlets reported as giving 4 positives with Toxin A we only got 2 positives with a similar dilution, 1 in 1000 of Toxin B.

These examples could be multiplied. Our final choice lay with Toxin B (Toxin No. 1 of McCartney's series). It gave positive results with all the early scarlets in our initial trials, negatives in convalescent scarlets that we were satisfied had been typical cases clinically, and it seemed to be giving a fair proportion of positives in our diphtheria patients. The reaction itself was clear-cut, very few ambiguous or difficult readings being found—the reaction on one occasion being very easily read in a negro baby. Finally the organism was derived from the type of scarlet prevalent in our district. From evidence which is accumulating this would not appear to be a point of great importance, but in view of our knowledge at the time we thought it well to be on the safe side.

Criteria of a Satisfactory Toxin Preparation.

A point that will be uppermost in the minds of those who have become interested in this work and propose to investigate the test for themselves, is the question of the potency of the filtrates used in the test. This will apply especially to those who have experience in the Schick test, where the toxicity of the test-substance can be estimated with great precision. Since, unfortunately, up to the moment of writing, no laboratory method has been devised for the standardisation of the toxin preparation used in the Dick test (chiefly owing to the extraordinary and complete absence of response on the part of laboratory animals to the filtrates), it is essential that workers should have some criterion of a satisfactory toxin, and the optimum concentration in which that toxin is to be used. Although I am aware that I am treading on contentious ground, I would venture to suggest that each toxin should be tried out on the basis of its behaviour towards the disease itself. That at least gives us a starting-point. Different dilutions of a filtrate should be employed by those experienced in intradermal work, and that one selected for further exploitation which gives first, at least 95 per cent. of positives in early scarlets before the end of the fifth day, and secondly, at least 70 per cent. of negatives by the thirtieth day. As we have seen in a previous experiment, the use of a more powerful toxin simply increases the percentage of positives in the later stages of the disease. But we already know from our experience with blanching tests, and from the therapeutic application of convalescent sera, that by this time the immunity response has become considerable. It would be wise therefore to take this fact into consideration if we are to regard the Dick test as a measure of immunity to scarlet fever. It is not to be supposed that these figures should be rigidly adhered to. They are simply put forward as a suggested scheme for gauging an appropriate toxin, and the strength in which it should be used. For example, the negative percentage of 70 is, of course, a purely arbitrary one, and as our knowledge of the immunity process increases will require no doubt to be modified. As will be noted subsequently my percentage of negatives in the convalescent stages is much higher, but it seems safer to err on the side of using too strong a toxin than too weak, particularly if the toxin is to be employed later on as an indicator of immunity conferred by the injection of toxin.

It is obvious, of course, that the value of such observations must depend on the number of cases tested and the accuracy of technique. Undoubtedly the latter is a matter of first-class importance, for as we have seen, the doubling of the dose of toxin had a marked effect on the positive rate. Comparable results might be introduced unless very great care was exercised in the measurement of doses, by imperfections in syringes, and so on. The above procedure would limit the titration of filtrates to workers in fever hospitals willing to take the responsibility. In the present state of our knowledge I do not see what other course is open to us.

Method of Applying the Test and Observing the Reaction.

The filtrate was supplied in a dilution of 1 in 100 and kept in the ice-chest until required. On each occasion that a series of patients was to be tested I made up a 1 in 1000 dilution sufficient for the test. A similar quantity of the same dilution was made up to act as a control. This was inactivated by heating in the water-bath for one hour at 100° C., any loss that occurred in the process owing to evaporation being made good by the addition of sterile distilled water. These diluted filtrates, active and inactivated, were employed throughout in a test dose of 0·1 c.cm.

---

[1] THE LANCET, 1925, i., 230.

Practically every series of individuals in whom the test was done consisted partly of scarlets, both early and late, and some other class of patient suffering from diphtheria, measles, whooping-cough, and a small number from chicken-pox. It was felt in this way that if the results in the scarlet patients were working out as they should, the results in the other class could be accepted as reliable. Readings were made of the reaction at intervals of 8 hours and 24 hours from the time of making the test. This was found necessary, as a number of cases that were definite positives at the eight hours reading had disappeared at the 24-hour interval, while it was also found that definite positives at the end of the 24 hours had been indefinite, or even quite absent, at the earlier reading. Generally, however, as most workers have already noted, the reaction was quite visible at the end of five or six hours, and in one case of a lady medical student who drew my attention to it, I saw a brilliant reaction at the end of an hour and a half standing out prominently from the surrounding exanthem. At the beginning of the work in a series of cases, 48-hour and 72-hour readings were also made, but it was decided that these were unnecessary, although it gave an opportunity of noting in a few cases pigmentation after the original brightness of the reaction had faded. I should also add in this connexion that I saw a case recently in a nurse where a reaction was quite definite in the test area and completely absent from the control area at the end of 48 hours. The routine readings were definitely negative at 8 and 24 hours, and she had given a history of having suffered from scarlet 15 years previously.

With regard to the reaction itself there is little to add to the former description given by Ker. Attention has been drawn to the occurrence of a "partial" positive by Okell and Parish,[2] by which is meant a reaction from half to a quarter as large as the usual size. Similar reactions were observed, especially in scarlets about the third week, and were noted as weak positives. In the tables given in this paper they have been included as positives, since in most cases in which this type of reaction occurred in scarlet when the test was repeated at a later date it was definitely negative. I believe, however, that such a result denotes a certain degree of immunity, as in one case in which such a reaction occurred the serum was secured for a Schultz-Charlton test, and produced a certain amount of blanching.

In my experience of the test, having been chiefly in children, pseudo-reactions have not been very common, and I cannot say that I have seen more than half a dozen, though on various occasions minor degrees of the phenomenon have appeared. It seems not unlikely the presence of pseudo-reactions depends on the nature of the protein present in the culture medium for preparing the toxin, which as used throughout this work was prepared from a rabbit blood broth, as previously described by McCartney.

Presence and Persistence of the Reaction in Scarlet Fever.

Table I. shows the results of 746 tests in scarlet patients, in many cases the test being made on the same patient at different stages of his illness. I have been able in this way to collect 110 cases who were tested on two, three, or even four occasions, and all of whom gave positives in the early stages, and later became negative. The percentage of 95·15 of positives in early scarlets is highly satisfactory, and the gradual diminution of these towards the thirty-fifth day is also striking.

Dealing with the large number of notifications of scarlet fever as we do in Edinburgh, allowance must be made for a certain small percentage error in diagnosis. That would account partially for the anomalous results at either end of the illness. But it must also be mentioned that not all the cases that were typical scarlets clinically developed a negative in convalescence. For instance, one case which was tested on the ninth and fifty-first days, and on two separate intervening occasions, remained consistently positive. On the other hand, special notes are available of two cases where consideration of the fact that positive Dick tests were obtained throughout the illness cast doubt on the diagnosis, inasmuch as it had been reported at the time of their appearance that the rashes were not convincing and desquamation not characteristic. Another experience of these persistent positive reactions is worth recording. During the time this work was in progress three cases were admitted to the wards notified as scarlet, but continued to show positive reactions. All developed definite attacks of scarlet while in the ward, and thereafter the reaction became negative. One of these, however, was a typical scarlet on admission, and I have not the least doubt that this was a true relapse. On reviewing the case notes of the other two the impression was obtained that there may have been room for doubt with regard to the original diagnosis.

TABLE I.—*Showing the Persistence of the Dick Reaction during Five-daily Periods of Scarlet Fever.*

Day of disease.	Total number of cases.	Positive.	Negative.	Percentage positive.
1–5	103	98	5	95·15
6–10	110	87	23	79·10
11–15	103	57	46	55·33
16–20	101	33	68	32·67
21–25	116	19	97	16·38
26–30	82	9	73	10·97
31–35	66	3	63	4·76
36–139*	65	4	61	6·15

* All others tested.

Fourteen cases came under my notice of patients taking scarlet fever whose reaction to the Dick test had been previously determined as positive. As an offset to this, one case of scarlet occurred in a patient whose reaction had been read as negative.

Incidence of Dick-positives in Individuals not Suffering from Scarlet Fever.

These tests were performed on patients in the diphtheria, measles, whooping-cough, and chicken-pox wards. The total number, 634, is perhaps small enough to generalise upon, but I must confess to a little disappointment with the findings, considering how well the toxin was working on the scarlet side, when I saw how the results worked out. (Table II.)

TABLE II.—*Showing Results of the Dick Test in 634 Individuals not Suffering from Scarlet Fever.*

Age period in years.	Total.	Positive.	Negative.	Positive percentage.	Positive percentage in diphtheria patients.
0–½	10	2	8	20	—
½–1	28	15	13	53·57	33·3
1–2	64	38	26	59·37	64·2
2–3	87	52	35	59·77	64·7
3–4	50	30	20	60	72
4–5	53	30	23	56·60	72·2
5–10	150	77	73	51·33	63·1
10–15	74	30	44	40·54	36·6

40–50	4	1	3	25	—
	634	304	330	47·95	—

It will be seen at once from the table that the percentage positive rate nowhere approaches that given by Zingher as the result of his investigations in New York.[3] He found as many as 70 per cent. in his most susceptible age-group, 1–2. Ker, McGarrity, and McCartney found their highest positive percentage rate, 67·8, in the 2–3 age-group. While my figures bear out the expectation that the highest percentages appear at the time when scarlet fever is most likely to occur, I had been hopeful of results more closely approximating to Zingher's. It should be borne in mind, however, that the total number of persons examined contains a large proportion of measles and whooping-cough patients, 285 out of 634, very nearly one-half of the total. These patients are recruited from the less well-to-do section of the population, and might be expected, as Zingher has already demonstrated, to contain a high proportion of non-susceptibles. I accordingly worked out the percentages in 349 diphtheria patients, and have included them in a separate column. They show a much higher incidence of positives, and indicate, what Ker concluded from his figures, that children take longer to acquire their immunity in this country, and also what those responsible for the conduct of fever hospitals are only too painfully aware of from time to time—namely, the very high susceptibility of these patients to scarlet fever.

---

[2] THE LANCET, 1925, i., 712.

[3] Jour. Amer. Med. Assoc., 1924, lxxxiii., 432.

Included in Table II. are the reactions of persons giving a previous history of scarlet. These numbered 76, of whom 67 were found negative, a satisfactory percentage of 88·15.

Relationship between the Dick Test and the Schultz-Charlton Phenomenon.

It was anticipated that some interesting results might emerge from a comparison of the Dick test with the results of injecting the serum from the same patient intradermally into the rashes of acute scarlets. In all 27 sera were tested in this way, involving the performance of 54 Schultz-Charlton tests. Each serum was tested on two bright rashes in typical scarlets, the amount of serum used varying from 0·5 c.cm. to 1 c.cm. in each rash.

The first series of cases consisted of patients in the 4th, 7th, 21st, 28th (two cases), 36th, 57th days of disease, and one with a previous history of scarlet at a remote date. Serum from the first three cases mentioned, who were positive Dick reactors, failed to blanch the scarlet rashes on which they were tried, and though carefully watched for, especially in the first two cases, there was no appearance of the reaction described by Blake and Trask. These authors described a reaction, similar to that of the Dicks, produced in susceptibles by injecting intradermally serum obtained from early cases of scarlet fever. One of the 28th day cases, the 36th day case, and the patient with a previous history of scarlet gave negative Dick reactions, and their sera gave excellent extinction phenomena in all rashes. The 57th day case and the other 28th day patient, both typical scarlets clinically, were Dick positive, but their sera produced blanching in every case.

The next series of cases consisted of two groups of 9 patients in each, one group being negative, the other positive Dick reactors. All gave a history of not having suffered from scarlet. The sera from the negative reactors succeeded in all cases in blanching the rashes upon which they were tried; the sera from the positive reactors failed in every instance.

Finally a serum was tried from a case which had given a weak positive reaction. In both rashes in which it was tried blanching was produced.

Apart, therefore, from the two exceptions in the first series, a definite correlation was established between the Dick test and the Schultz-Charlton phenomenon. The surprising thing to me is that there were not more exceptions, because there can be no comparison between the delicacy of the tests. Assuming that by the Dick test we can estimate individual immunity to a specific hæmolytic streptococcal toxin, the amount of toxin used in the test is purely an arbitrary one, and it is reasonable to suppose that a person might give a positive reaction and yet his serum contain sufficient antibody in the comparatively large amount of serum employed in the Schultz-Charlton test to neutralise the toxin over the comparatively limited area affected by the intradermal injection.

Blanching Effects of Antitoxic Sera.

Dr. O'Brien was anxious that we should experiment with his antitoxic sera with a view to investigating their capacity for extinguishing scarlet rashes. In the experiments detailed below, only rashes varying from bright to brilliant were employed, none were later than the third day of disease, and the intradermal dose in every case 0·5 c.cm. in the skin of the pectoral region. Where neat serum was employed, the test was controlled with a scarlet serum known to produce blanching, and with normal horse serum. No higher dilutions than the ones mentioned were tried.

Serum A 4156 was used in three cases undiluted, on two in a dilution of 2 in 5, and in three in a dilution of 1 in 10. Blanching was produced in every instance. In a case of facial erysipelas in the early stages, with a well-marked spreading margin, 0·5 c.cm. of this serum was injected intradermally half an inch beyond the raised edge in two separate sites. In 16 hours the edge had passed over both injected areas, and the erysipelatous flush in the neighbourhood of the needle marks remained of the same intensity as the rest.

Serum A 4200 was tried in one case undiluted, and in two cases in a dilution of 1 in 200. In the former case and in one of the cases where a dilution of 1 in 200 was employed blanching was observed. In the other case, which had a brilliant rash of the "boiled lobster" type, no extinction appeared, and it is of interest to note that this patient gave a positive Dick reaction on his 9th day, which was negative on the 23rd day of his disease.

Serum A 4177 was tried undiluted on two cases, in a dilution of 1 in 50 in two cases, in 1 in 100 in two cases, and in 1 in 200 in four cases. In every instance blanching was observed.

In all cases in which the neat antitoxic serum was used the control convalescent scarlet serum produced blanching, while the normal horse serum produced no effect in the direction of blanching. In three instances, however, the horse serum caused irregular areas of blotchiness.

From time to time in experiments with the Schultz-Charlton test I have noted that with serums obtained from various patients the area and the depth of the blanching has shown a certain degree of variation. While this may be partly attributable to the differences in level at which the needle was introduced, there can be no overlooking the possibility of different immunity responses on the part of various individuals to the disease. In the above cases in which undiluted serum was used one could not fail to be struck by the fact that the blanching effect was more marked than that usually brought about by a convalescent serum.

In two cases, both when serum A 4156 undiluted was injected, there appeared areas of blotchiness at the periphery of the blanching, and also encroaching irregularly on the blanched area. In neither case was the extinction phenomenon masked by this appearance.

Effect of Antitoxic Serum in Neutralising Toxin.

This experiment was undertaken to determine the effect of mixing antitoxic serum with the filtrate used in the tests reported in this paper. Twelve diphtheritic patients were chosen who had given good positive reactions four days previously. The test mixture consisted of 0·5 c.cm. toxin (1 in 100), 3·5 c.cm. normal saline, and 1 c.cm. serum of A 4156. A control mixture was made up by adding 0·5 c.cm. toxin (1 in 100) to 3·5 c.cm. normal saline, heating for one hour at 100° C., and making up to the original bulk of 4 c.cm. by the addition of sterile distilled water. After cooling 1 c.cm. serum A 4156 was added. The test and control mixtures were allowed to stand at room temperature for ten hours before use. In this way the toxin was at its usual concentration of 1 in 1000, and the antitoxic serum in a dilution of 1 in 5.

Of the 12 children tested in this fashion eight gave straight negatives, two gave combined pseudo-negatives at the eight hours reading, and one a combined pseudo-negative at the 24 hours reading. The remaining case showed nothing at the eight hours reading, but at 24 hours a reaction was present in both test and control areas, the test reaction being slightly larger than the control. The net result was, therefore, that in 11 out of 12 cases this serum was able to prevent the toxin reacting.

Passive Immunity with Antitoxic Sera.

Having definitely assured myself that these sera could extinguish scarlet rashes, and of the capacity of one of them to neutralise the toxin I was employing in my routine testing, I next turned my attention to passive immunity experiments with two of these sera.

The first group consisted of eight patients who at some previous date had been found positive. This was confirmed by retesting and each received 5 c.cm. serum A 4200 intramuscularly. An interval of 24 hours was allowed to elapse and all were again tested. Two of the eight were found negative, the remainder positive. Retested at the end of four days all were positive, one of the previous negatives only showing a weak reaction however. Bearing in mind the failure of Ker to achieve a passive immunity with 5 c.cm. of convalescent serum I considered the possibility of my dosage being too small, and tried another batch of four Dick positive patients with an intramuscular injection of 10 c.cm. of the same serum. The 24-hour and the fourth day retests were all positive. Three other Dick positive patients were thereupon given 20 c.cm. intramuscularly. Two gave positive reactions at both 24-hour and 4th day retests, while the third was negative at the 24-hour and weakly positive at the 4th day retest.

Another serum, A 4177, was employed with better results. Following the same procedure with regard to the retesting of 14 cases previously giving positive reactions, I followed by injecting 10 c.cm. intramuscularly. At the 24 hours retest I found all except one were Dick negative, and this individual remained positive at intervals of four and eight days. At the 4th day retest 13 were still Dick negative ; at the 8th day retest four more positives reappeared, whilst two having been discharged from hospital, seven negatives were left. On the 11th day after receiving the serum three of these seven were now positive ; two had left hospital, leaving two negative. These negatives were not again retested till the 18th day, when both were found positive.

The above results are interesting in view of the failure of serum A 4200 and the comparative success of A 4177. Unfortunately only two blanching experiments were done with A 4200 in a dilution of 1 in 200, but it seems noteworthy that it should not have succeeded in one of two cases, whereas the more successful serum A 4177 should have been able to extinguish all of four scarlet rashes in the same dilution.

Conclusions.

1. In performing the Dick test the choice of toxin is a matter of great importance, and careful preliminary trials are necessary before embarking on testing on a large scale. From variations in the number of positive reactions obtained by the use of filtrates from different strains of organisms, and by the same filtrates in different dilutions, it is suggested that the reaction is quantitative. The particular toxin selected was employed in a dilution of 1 in 1000, the test dose being 0·1 c.cm. intradermally.

2. The reaction with the particular toxin employed required to be read on two separate occasions, intervals of 8 and 24 hours having been found the most suitable times.

3. Scarlets in the first five days of illness yielded a positive percentage of 95·15 per cent., whereas from the 31st to the 35th day of illness 4·76 were found positive. Between these two periods there was gradual declension in the positive percentage rate.

4. In 634 patients not suffering from scarlet the highest percentage positive rate was 60, obtained at the 3–4 age-period, the age-periods showing the next highest incidence being between 2–3, 1–2, and 4–5, in the order given, all these showing a percentage positive rate of between 55 and 60. In persons with a previous history of scarlet 88·15 per cent. were found negative. The Dick reaction had been previously determined in 15 patients who subsequently took scarlet, and of these 14 were positive, the other having been noted as a negative reactor.

5. A correlationship was established between the Dick test and the Schultz-Charlton phenomenon in 25 out of 27 cases.

6. Three antitoxic sera were tested with regard to their ability to extinguish scarlet rashes. One blanched in all cases in dilutions up to 1 in 10, another in all cases up to 1 in 200, while a third succeeded in one case when undiluted, and in one case in a dilution of 1 in 200, but failed in one case in a dilution of 1 in 200.

7. An antitoxic serum in a dilution of 1 in 5 was able to neutralise the action of the filtrate employed throughout these tests, as judged by its capacity to prevent the filtrate reproducing the reaction in 11 known positive reactors out of 12.

8. Passive immunity experiments were undertaken with two antitoxic sera. One practically failed in doses of 5 c.cm., 10 c.cm., and 20 c.cm. intramuscularly. The other succeeded in 10 c.cm. doses intramuscularly in producing a passive immunity lasting in 13 out of 14 cases up the 4th day, in seven cases up to the 8th day, and in two cases up to the 11th day.

I would like to place on record my appreciation of the help given by the resident and nursing staff of the City Hospital, Edinburgh, whose coöperation in a time of stress alone rendered this work possible. Also to Dr. McCartney for a never-failing supply of toxin, to Prof. T. J. Mackie for much helpful advice, and to Dr. O'Brien for his generosity in supplying various preparations.

THE DICK TEST AT A FEVER HOSPITAL.

By F. A. E. SILCOCK, M.D. Belf., D.P.H.,
MEDICAL SUPERINTENDENT, ISOLATION HOSPITAL AND SANATORIUM, LEICESTER.

Scarlet fever is thought by many now to be a localised disease of the nasopharyngeal mucosa, due to a certain specific strain of hæmolytic streptococcus which produces a toxin locally which is absorbed into the blood-stream, giving rise to the constitutional symptoms and the erythematous rash.

Where secondary infection occurs it is due to the action of the toxin so formed and absorbed lowering the resistance, and thus making the patient an easy prey either for the hæmolytic streptococcus itself or for any of the other nasopharyngeal bacteriological inhabitants. Immunity to scarlet fever must be antitoxic mainly, and cases in which a secondary rash develops during the course of an attack might be explained by the fact that this specific antitoxic immunity had not been developed sufficiently or not at all, and instances of a second attack might be explained in a similar way. As one attack usually confers immunity it would appear that the immunity is mostly antitoxic in nature. In my opinion the comparative immunity shown by adults might be explained, on this hypothesis, by the fact that adults usually have a good antitoxic immunity to scarlet fever, as is evidenced by the fact that the constitutional disturbances resulting from an attack of this disease are usually less marked in adults than children.

The Dick Test for Susceptibility to Scarlet Fever.

Dick and Dick[1] first described an intracutaneous immunity test for scarlet fever, using a soluble toxic filtrate of an hæmolytic streptococcus obtained from cases of that disease. Various modifications in the manner of preparation of this toxin have been recommended. Through the kindness of Dr. Abraham Zingher, of the Department of Public Health, New York, U.S.A., I was supplied in September, 1924, with some of the toxin recommended by him. Zingher's method of preparing it is briefly as follows. Pneumococcus broth containing 5 per cent. citrated horse blood is inoculated with a 24-hour-old culture of the specific hæmolytic streptococcus. This is then incubated for five days and then removed from the incubator and 0·5 per cent. carbolic acid is added to the culture. The resulting precipitate is allowed to settle, and the supernatant fluid decanted and forms the toxin.

The Toxin.—The strength of toxin requisite for the skin test is estimated by comparing the relative results *re* its local action on the skin of a susceptible person in known dilutions. The diluent used is physiological normal saline solution. In the case of the particular toxin used by me the dilution was 1 in 1000. The toxin keeps well both diluted and undiluted, if kept in a cool, dark place, and I found it as potent after eight months as when fresh.

Control.—This is made by heating the toxin as prepared above in a water-bath for one and a half hours at 100° C., and then allowing it to cool.

Technique of the Test.—The skin on the anterior aspect of the middle third of both forearms is cleaned with ether soap and then with ether. 0·2 c.cm. of the diluted toxin is injected intracutaneously into the left forearm, and a similar amount of the diluted control into the right forearm. I used an "Agla" hypodermic syringe, and number 26 gauge rustless steel needles. When the injection has been made there appears immediately at the site of it a raised white weal, varying in diameter from 7 to 10 mm. in diameter. The openings of the cutaneous glands show as small depressions in this weal, and the latter disappears in five minutes or so. Readings of the test and control areas were taken in every case at 6, 12, 24, 48, and 72 hours from the time of injection.

Table I. gives the results of the Dick test on cases clinically diagnosed as scarlet fever at different stages of that disease. The figures show that the majority gave a negative reaction on and after the tenth day of scarlet fever; 190 cases were tested from the tenth day of illness onwards with the results shown in Table II.

TABLE II.

Stage of disease.	Total number positive.	Percentage positive.	Total number negative.	Percentage negative.
10 days and over ..	22	11·6	168	88·4

Many of the scarlet fever cases gave a positive reaction up to the tenth day of disease, after which the majority gave a negative reaction. In most of the positive cases during the first five days of the disease the reaction was distinct (+), and in a few cases a markedly positive one (++). After five days practically all cases gave a gradually less marked positive reaction till after the tenth day, when 88·4 per cent. gave a negative one. I noticed that in severe cases with marked rash and early and well-marked desquamation a negative reaction was developed sooner than in mild cases. One case gave a positive reaction on the nineteenth day of disease, and also again on retesting ten days later, although desquamating when tested, and admitted with a good scarlatiniform rash and mild symptoms to hospital. A similar case was noted on the twenty-fifth day of disease, the reaction remaining positive although desquamating. These two cases might be examples of persons who do not develop antitoxic immunity even though attacked by scarlet fever.

Sixty-five cases were retested one or more times later during convalescence, owing to the fact that there was either an element of doubt *re* original diagnosis or the Dick test when first applied was positive, and might become negative later on. Five cases gave a persistently positive reaction, and did not desquamate or show any complications suggestive of scarlet fever.

In Table III. a comparison is given of the results of the Dick test on 281 cases of scarlet fever as tested by Zingher[2] at the Willard Parker Hospital, New York, and 254 similar cases tested by the same toxin at Leicester Isolation Hospital. From this table it would appear that antitoxic immunity is developed more slowly in Leicester than in New York, but that in the end the former cases develop a greater percentage of immunes. This is possibly accounted for by the fact that well-marked cases are rare in Leicester, and the present type of case is mild and, therefore, it takes longer for it to develop sufficient antitoxin to become immune. I have already remarked on the earlier development of a negative reaction in well-marked cases with a good rash and early desquamation.

Results of Dick Test on Cases of Diphtheria Undergoing Treatment.

I performed this test on 132 cases of diphtheria, composed as follows: faucial (diph.), 99; nasal and faucial (diph.), 19; nasal (diph.), 5; laryngeal (diph.), 3; faucial and laryngeal (diph.), 2; faucial carriers of diphtheria, 4.

Of this number three cases, all from one family, were suffering from well-marked scarlet fever and faucial diphtheria concurrently, and all three gave a negative reaction Seven of the cases had had scarlet fever previously and all gave a negative reaction. Amongst this group my personal experience of the test might be worth mentioning. Whilst carrying out these tests I was warded with faucial diphtheria, and, having had scarlet fever six years previously, I thought it would be interesting to see if at any period during my attack of diphtheria I would give a positive reaction. Although I tested myself on six different occasions I always gave a negative reaction to the test. I might add that I had on three occasions, previously to contracting diphtheria, performed the test on myself with a similar result. Four of the diphtheria cases were faucial carriers only, and all gave a negative reaction. One diphtheria case giving a negative Dick reaction had been detained in hospital 108 days for complications, when tested, and his throat condition was quite healthy. This case would presumably not be specially susceptible to scarlet fever, as it was well over the convalescent period of diphtheria. Allowing for the last three groups (comprising 12 cases) as not being specially susceptible to scarlet fever, or having had that disease previously, we get 120 cases of diphtheria remaining.

In Table VI. the results are given of the Dick test on 120 cases of clinical diphtheria (all without a previous history of scarlet fever).

F. = faucial. N. = nasal. L. = laryngeal.

Table VII. gives the result of the Dick test in diphtheria cases—all age-groups—as displayed by different types of that disease. From this table it will be noted (1) that the most susceptible age-group in diphtheria to scarlet fever is the period 3 to 6 years; (2) the age-group 20 years and upwards, at which there is usually a lessened susceptibility to scarlet fever in normal persons, is least affected by the incidence of diphtheria; (3) nasal as well as nasal and faucial cases would appear specially prone to scarlet fever; (4) the immunity conferred by a previous attack of scarlet fever holds good, even if one contracts diphtheria at a later date they would not appear again susceptible to scarlet fever; (5) the four faucial diphtheria carriers all gave a negative Dick reaction, but whether there is a common antitoxic immunity or not could not be said from such a small number of cases.

TABLE VII.

Region affected.	Number tested.	Dick-negative.	Dick-positive.	Percentage positive.

Totals	120	41	79	65·8

Table VIII. gives the relative susceptibility to scarlet fever of normal persons and of diphtheria cases—in age-groups—as shown by the Dick test. From this table it would appear that there is a marked increase in susceptibility to scarlet fever shown by diphtheria cases as a whole, as well as at every age period.

TABLE VIII.

Age-group in years.	Percentage positive—		Percentage increase.
	Normal cases.	Diphtheria cases.	
1 to 3	Nil	60·0	60·0
3 to 6	65·0	84·4	19·4

20 and over ..	21·05	35·0	13·9
Totals	47·74	65·8	18·06

In Table IX. the Schick test for susceptibility to diphtheria was performed on 105 cases of scarlet fever undergoing treatment with the results shown. From the figures in Table IX., contrasted with those in Table VIII., one sees that there is an increased susceptibility to scarlet fever shown by diphtheria cases as a whole, as compared with that shown by scarlet fever cases to diphtheria; the percentage being 65·8 for diphtheria cases to scarlet fever; 58·09 for scarlet fever cases to diphtheria; 7·71 increase for all age-groups.

General Observations on the Dick Test in Diphtheria Cases.

(1) The test appears to be as reliable an index of susceptibility to scarlet fever in these cases as in ordinary normal individuals, and in all cases with a previous history of scarlet fever a negative reaction was noted. (2) Both in normal persons and in cases suffering from diphtheria there is a very small percentage of positive reactors above the age of 20 years. (3) In four cases an antitoxin (diphtheria) serum rash developed at the same time as the Dick reaction was manifest. This did not interfere with the readings, and the former faded in all cases before the latter, leaving the reaction well marked. (4) The reaction seemed much better marked and defined from the surrounding normal skin area in diphtheria cases than it did in both normal and scarlet fever cases. (5) In 21 cases out of the number of diphtheria cases tested there was a well-marked positive reaction (+ +) = 17·5 per cent. of marked positives. (6) The number of pseudo reactions (both negative and positive) was less than in scarlet fever and normal cases.

Five cases of erysipelas were tested by the Dick reaction also. Of this number four were cases of the facial type and one of the leg. The latter case gave a positive reaction on the third day of illness, and a negative one when tested on the twenty-seventh day of illness. All the remaining four cases gave negative reactions. It might appear that there is some relationship between scarlet fever and erysipelas, but owing to insufficiency of clinical material it would be impossible to draw conclusions till a much larger number of cases had been tested. Clinically the two diseases have often appeared to me to be allied.

The Dick Test as an Aid to Diagnosis of Scarlet Fever.

(1) A positive reaction during the first ten days of illness, gradually getting less markedly positive from the fifth day, would be in favour of a diagnosis of scarlet fever—more especially so if the reaction became negative after the tenth day. (2) A positive reaction persisting after the tenth day of illness would be against the diagnosis of scarlet fever, as also would a markedly positive reaction after five days. (3) The results of the Dick test in normal people bears out the statistics as to the age-incidence of scarlet fever—e.g., a positive reaction during the first ten days of illness in a suspected case, aged 25 years or over, would be in favour of the diagnosis of scarlet fever.

In conclusion I would like to express my thanks to Dr. Zingher, and also to Dr. Okell, of the Wellcome Research Laboratories, Kent, for their kindness in forwarding me samples of Dick toxin for carrying out the tests. I found that the former's preparation gave better results with our cases, and all of this series were tested with it.

SOME PROBLEMS CONNECTED WITH THE DICK TEST.*

By R. A. O'BRIEN, M.D. Melb.,

and

C. C. OKELL. *M.C.*, M.R.C.P. Lond.

(*From the Wellcome Physiological Research Laboratories, Beckenham.*)

We know from the results of recent work in England, which broadly agree with those obtained in America, that the Dick toxin with which we are working is specifically related to the scarlet fever prevalent here. In the first few days of the disease a suitable dilution of the toxin will give a high percentage of positive reactions; these same patients will during convalescence change their reaction from positive to negative; the toxin is neutralised by the serum of patients convalescent from scarlet fever, and the toxin, if given in sufficiently large doses to volunteers, will produce what is in some essential characteristics (temperature, vomiting, and rash) a miniature attack of scarlet fever. We know also that the serum of horses immunised with this toxin contains an antitoxin giving the specific Schultz-Charlton reaction. We may go further and say that the accumulating evidence leaves little doubt that, at least in certain severely toxic cases of the disease, the antitoxin has a definite therapeutic effect. There are, however, a great many points still unexplained, and it is by the close study of these that progress will be made.

It is necessary to avoid changes in toxin while doing experimental work; one must, therefore, have a large volume of liquid toxin available. Scarlet fever toxin is strikingly resistant to heat, and of a much higher order of stability than other well-known bacterial toxins. It is not known at present whether dried toxin, or toxin precipitated by one of the well recognised methods of precipitation, would be more stable than the liquid toxin. Presumably it would be.

The Question of Dilution.

We know fairly closely what are the most suitable dilutions of toxins for use. The question is an interesting one. As Park has pointed out: "If a toxin is a little too strong there will be too many positives; if it is too weak there is a possibility of having people who are susceptible pronounced as immune."

We commenced working with a dilution of 1/6000 of our large bulk of toxin, for with this dilution several of the laboratory staff gave clear positive reactions. Several physicians in fever hospitals have kindly compared the two dilutions 1/6000 and 1/1000. One worker found in the first week of scarlet fever 12 per cent. of positive reactions with dilution 1/6000, while a 1/1000 dilution gave 60 per cent. of positive reactions; for the second week the figures were 6 per cent. and 12 per cent. It is therefore evident that 1/1000 is the better strength to use when testing patients considered to be suffering from scarlet fever. It may, of course, not be the optimum.

Percentage of Positive Reactions.

Different observers, when testing patients admitted in the first two days of the disease, have obtained different percentages of positive reactions. Most workers give a percentage of from 66 to 100, while two clinicians, working with small groups of patients, obtained percentages as low as 22 and 42. Probably a close study of these differences would give information of value. The change from a positive to a negative response to a 1/1000 dilution of the toxin during the disease appears to occur in the average case about the fifth to the eighth day. One point of some interest is that amongst 673 reactions there were but 10 (1·5 per cent.) "pseudo and positive," and 25 (3·7 per cent.) "pseudo and negative." This low percentage we probably owe to the fact that Okell and Watson chose for the growth of the streptococcus ordinary digest medium containing no blood, and, from a study of the growth and metabolism curves, harvested the toxin at 18 hours.

With a 1/1000 dilution of toxin the percentage of positive reactors in different ward staffs varied from 7·5 in a large hospital (106 nurses) to 10 amongst 31 nurses and probationers. Evidently the great majority of nurses of long experience in scarlet fever wards are negative to the Dick test and non-susceptible to the disease. We do not know accurately what percentage of nurses in such wards would give a history of having contracted scarlet fever during their hospital life. It is probably fairly large, but many have no such history. Evidently, as in diphtheria, nurses (and others) may become immune through minute unrecognised infections with the scarlet fever organism. Nurses with positive reactions are generally newcomers. Two nurses in fever hospitals who gave a positive response to the test developed scarlet fever later. We would not be surprised to find that practically every nurse who has been several years in scarlet fever wards has either suffered from an attack of the disease during her hospital career or has already become immune from unrecognised infections either during or prior to life in the wards.

Significance of a Negative Response.

We know broadly that a negative response to the Dick test indicates a high degree of non-susceptibility, but we are not convinced that a positive, and particularly a "partial positive," reactor may not possess some immunity. It will be of great interest to ascertain how high the immunity represented by a negative reaction is. We have already reported that in one hospital, during a certain period, eight patients wrongly diagnosed as suffering from scarlet fever who gave a negative Dick reaction were admitted to the scarlet fever ward, but none developed the disease from ward infection, whereas of six positive reactors similarly admitted four developed the disease within a short period of admission to the ward. In another hospital a case of scarlet fever made its appearance amongst a group of 50 convalescents who were closely associated; 37 of these were "Dick-negative," none developed the disease, while of 13 who were "Dick-positive," six developed scarlet fever. On the other hand, we have notes of two instances in which patients were apparently negative to the Dick test when 1/1000 dilution of toxin was used, yet shortly afterwards developed an attack of what was considered to be typical scarlet fever. Such instances do not materially affect the main thesis; for the moment we simply place them on record.

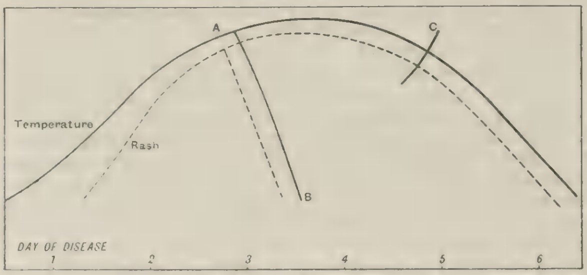
---

* A paper read at a meeting of the Fever Group, Society of Medical Officers of Health, Nov. 27th, 1925.

With regard to the application of the Dick test to diagnosis in the disease, it will be necessary to get a clear idea of the immunity curves of the disease. This will not be completely and satisfactorily done until one can as easily measure the toxin and antitoxin of scarlet fever in the laboratory as those of diphtheria. We have constructed a hypothetical curve which may well record what happens during an attack of scarlet fever.

In Curve 1 the heavy line diagrammatically records the temperature and toxæmia in an ordinary attack of scarlet fever, while the interrupted line records the development of the rash. Results recorded in England, as well as many observations from America, justify one in saying that if one gives at point A a sufficient dose of scarlet fever antitoxin produced in the horse, the temperature and rash will rapidly fall as at B, and the patient's serum will be found to contain sufficient antitoxin to give the Schultz-Charlton blanching in fresh cases of scarlet fever. We may therefore reasonably assume that at point C in an ordinary case of scarlet fever, untreated with antitoxin, the temperature and rash rapidly fall, because the patient has himself produced a large quantity of antitoxin which has been made in those cells of his body that manufacture antitoxin, and has there accumulated until it has been given off into the circulating blood to such an extent that the patient's serum will now give a Schultz-Charlton phenomenon when tested on a fresh patient.

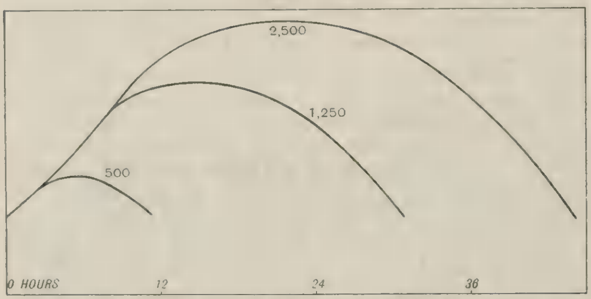
FIG. 1.



Scarlet fever.

Curve 2 represents observations made with our toxin. 500 skin reacting doses will produce either no temperature or a disturbance scarcely recognisable, and lasting only perhaps a few hours; 1250 doses will produce in some instances a miniature attack of scarlet fever—i.e., slight sickness, temperature, and rash, lasting 24 to 48 hours—while 2500 doses will produce in most instances vomiting, fever, and rash lasting about two days. We can from this get a quantitative idea of the *minimum* amount of toxin produced in an ordinary attack of scarlet fever.

FIG. 2.

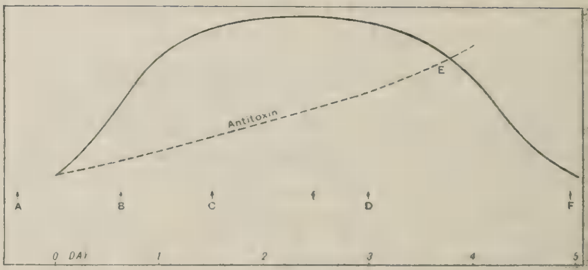


Miniature scarlet fever produced by toxin.

In Curve 3 we have represented what we conclude is occurring in an ordinary attack of scarlet fever. At point A—i.e., just before infection, or in the very earliest stage of the incubation of the disease before any symptoms have been produced—it is probable that weak toxin—e.g., 1/6000 dilution of our standard toxin—would yield a positive reaction. If we test again at point B the patient has begun to produce a minute amount of antitoxin in response to the toxin stimulation which has been going on for some 24 or 48 hours; we now find that the antitoxin is sufficient to neutralise a toxin dilution of 1/6000 but not 1/1000, for this latter dilution gives a positive reaction, while 1/6000 yields a negative. If we wait until point C we might find that the rapidly increasing antitoxin in the patient's blood or skin cells would neutralise a dilution of 1/1000 but not 1/200; at point D it might take 1/10 to produce a reaction; while at point E sufficient antitoxin has accumulated in the cells or blood to neutralise all the toxin secreted by the attacking organisms during the disease; and after point F the patient gives a permanent negative response.

We would suggest that attention should be concentrated on the study of the earliest period of the disease. If the patient is not admitted until the second or third day and gives a negative response to 1/1000 dilution, will he give a positive response to 1/500 or to 1/100? If when admitted on the second or third day he fails to give the Schultz-Charlton test when 0·2 c.cm. of 1/10 dilution of a good horse antitoxin is injected intracutaneously, will he give a positive Schultz-Charlton test when 0·5 c.cm. of 1/10 dilution is injected or even 0·5 c.cm. of undiluted horse antitoxin? (With this latter dose it would, of course, be necessary to use a control intradermic injection of undiluted horse serum containing no streptococcus antitoxin—e.g., diphtheria antitoxic serum.)

FIG. 3.



Scarlet fever.

Are There Different Types of Scarlet Fever?

Are all scarlet fever toxæmias due to the same toxin or are there different toxins in true scarlet fever—in other words, are there immunologically different types of the disease? One of us (C. C. O.) has long felt that there might easily be an overlapping of antigens beween the so-called true scarlet fever streptococcus and other streptococci, at least other hæmolytic streptococci. Recently a hæmolytic streptococcus, isolated by Sir Frederick Andrewes from a spreading lymphangitis of the arm, has yielded, when grown on the same media as the Dick and Dochez coccus, a filtrate which gives a typical positive Dick reaction in a known Dick-positive reactor, and a negative in a known Dick-negative reactor. We do not know yet if the toxin is neutralisable by true scarlet fever antitoxin. As yet the relationships between the various streptococci and their toxins have not been sufficiently investigated. This field is rich in interest.

Dr. C. Rundle has had the idea that there may be two or more types of scarlet fever, and has worked particularly by the Schultz-Charlton method. Furthermore, Dr. Park has in a recent paper suggested that there may be a wide antigenic overlap between the different streptococci, that—e.g., while the ordinary scarlet fever toxin contains antigenic or toxin components *a*, *b*, *c*, *d*, others may exist which contain *a*, *b*, *c*, *e*, and so forth.

It is stated that during convalescence after what seems to be typical scarlet fever a certain number of patients continue to give a positive Dick reaction. The point needs further investigation. If such patients exist, have they cured themselves of their fever by producing antitoxin which is still locked up intracellularly, and are the cells slow to excrete the antitoxin into the blood-stream? Will they become later negative to the Dick test? Have they responded to the primary stimulus of the toxæmia and, if injected with, e.g., 500 skin doses of toxin during convalescence, will they rapidly produce sufficient antitoxin to make them negative to the Dick test? These and many other interesting points can be worked out only by those having the opportunities of making clinical observations. In the laboratory, until a satisfactory test is discovered, we can do but little.

We may here mention an interesting question for investigation. How stable are the dilutions of toxin? We have considerable evidence that they are stable for at least two weeks. This is a small practical point, but one it is important to know in order to avoid fallacies in making a series of observations. It is obvious that the old and the new dilutions must be tested on the same subject.

THE HEPATIC ASPECT OF EPIDEMIC ENCEPHALITIS.

BY ELIZABETH O'FLYNN, M.R.C.P. LOND.,

AND

MACDONALD CRITCHLEY, M.D. BRISTOL, M.R.C.P. LOND.

(From the National Hospital for the Paralysed and Epileptic, Queen-square, W.C.)

THE association of hepatic cirrhosis with disease of the basal ganglia is well known, the outstanding example being found in Wilson's progressive lenticular degeneration. Other amyostatic syndromes, such as torsion dystonia, paralysis agitans, &c.—each presenting definite clinical features—are less clearly defined from the pathological standpoint, and it is doubtful to what extent, if any, hepatic derangement takes a part. Clinically, there is but little to suggest an insufficiency of the liver in the majority of instances—even in advanced cases of progressive lenticular degeneration. There are but scanty reports of chemical investigations as to the efficiency of the liver during life; the researches of Dresel and Levy on paralysis agitans and of Ivens on Wilson's disease suggest, however, that defective liver function does occur and can be demonstrated by laboratory methods, although absent clinically.

The object of the present investigation is to ascertain whether evidence exists, suggestive of hepatic involvement in the amyostatic manifestations of encephalitis. Most of the cases chosen have been examples of the Parkinsonian syndrome arising late in the course of a chronic progressive lethargic encephalitis.

Clinical Evidence of Hepatic Derangement.

It is rare to encounter, either during the acute or chronic manifestations of the disease, clinical evidence of hepatic derangement. Although continental writers have occasionally drawn attention to such phenomena, the experience of most English neurologists has been that encephalitis is rarely characterised by signs suggestive of liver involvement. Mlle. Lévy, however, in her recent monograph, states that she has observed jaundice several times in the course of the disease. Van Bogaert (1924) has recorded a case of post-encephalitic respiratory disorder in which jaundice appeared nine months after the onset of the illness, and persisted for a fortnight; there was no discoloration of the stools, but bile-salts were detected in the urine. Ottonello (1924) found signs of enlargement of the liver in eight out of 15 cases of Parkinsonism. Pedrinoni (1925) found clinically an increase in the hepatic dullness in several cases of chronic encephalitis; in one case the liver was apparently diminished in volume. Some ascites was found in one instance.

No clinical evidence was found in any of our cases to suggest a disordered function of the liver. We have never met with jaundice, ascites, pallor of the stools, or abnormal areas of hepatic dullness in any case, either during or after the acute attack.

Histological Evidence.

Unfortunately, there is but scanty reference in the literature of epidemic encephalitis to the post-mortem appearance of the liver. This fact alone suggests that an absence of gross naked-eye changes in that organ is the rule; the evidence of macroscopic cirrhosis is sufficiently striking at an autopsy to invite comment and more detailed examination.

Reports as to the microscopic structure of the liver in these cases are even rarer, and most of the records at our disposal are the work of Italian physicians. In one fatal case of epidemic encephalitis, in which the patient died three weeks after the onset, Ada Harris (1921) reported œdema, cloudy swelling, and fatty degeneration in the liver. The blood-vessels were engorged, a few of them showing perivascular hæmorrhages. There were areas of necrosis around some of the interlobular vessels. Pierantoni (1923) recorded an autopsy on a man of 29, dying in a state of Parkinsonism of three and a half years' duration. The liver was found to be markedly cirrhotic; there was no previous history of syphilis or alcoholism. D'Alessandro (1924) also found vascular stasis and incipient fatty degeneration in the liver of a fatal case of encephalitis.

Rizzo (1924) found in the liver of one case, which perished on the fifteenth day, patchy colliquative degeneration of the parenchyma. The blood-vessels were congested, and here and there were traces of fatty degeneration. No evidence of connective tissue reaction was observed. In two cases of Parkinsonism in chronic encephalitis, of two and a half and three years' duration respectively, he found definite histological changes. Patchy colliquative rarefaction of the parenchyma was observed; in one case there was some venous congestion. Both cases exhibited a definite connective tissue reaction of fibroblastic and fibrous character.

We have had the opportunity of examining the liver in two fatal cases of encephalitis.

Liver 1.—M. N., male, aged 56 (patient of Dr. Gordon Holmes).

(Very advanced case of Parkinsonism following encephalitis; acute onset three and a half years previously.)

Naked Eye.—The liver was normal in size and consistency, and of smooth surface.

Histological.—On microscopical section the capsule appeared slightly thickened. There was a little increase in fibrous tissue in the portal spaces and between the cells. This cirrhosis was universal except in the case of the intercellular increase, which was patchy in distribution and but slight in degree. Associated with this connective tissue proliferation there was a small round-cell infiltration of the portal spaces. No cells were present between the liver cells or around the blood-vessels. There was no dilatation of the ducts or canaliculi. The majority of the cells appeared healthy; in some there were fatty changes, the fat being present in large globules staining brick red with Scharlach R. The nuclei remained intact and were deeply stained. There was perhaps some diminution in the number of Küpffer cells, which in many places appeared flattened against the sinus walls. Bile-pigment was seen in the cells and ducts.

Liver 2.—L. B., male, 5½ years (patient of Dr. Wilfred Pearson).

(Acute onset of encephalitis 12 months before death. Patient gradually passed into a stage of chronic nocturnal chorea with diurnal lethargy; stiffness of legs; dysphagia; mouth gaping widely; marked respiratory arrhythmia. Gradual onset of unconsciousness with head retraction before death.)

Naked Eye.—The liver was normal in size, shape, colour, and consistency. No surface irregularity was present, and there was no thickening of the capsule.

Histological.—In this case there was little or no increase in the amount of fibrous tissue in the portal spaces, and no pericellular fibrosis whatever. There was no round-cell infiltration. The veins were slightly engorged ; the great majority of the liver cells were normal, but in some occasional traces of fatty degeneration were detected ; the fat was present in the form of very fine droplets, staining brick red with Scharlach R. No abnormality could be noted in the Küpffer cells.

These two livers afforded no evidence of impairment of any of the hepatic functions—secretory, excretory, glycogenic, or detoxicatory. The changes described are such as might be present in any fatal case of toxæmia, and there was nothing to suggest damage to any appreciable proportion of the liver cells.

Biochemical Evidence.

Various metabolic aspects of encephalitis have been studied, particularly by continental workers, who have concentrated upon the question of liver efficiency. In this country Ellis (1924) investigated the excretion of nitrogen and phosphorus in epidemic encephalitis. He found increased amounts of ammonia in the urine and an absence of phosphoric acid ; in many cases albumosuria was encountered. He considered these changes to be due to intestinal or more probably liver derangement. Meyer-Bisch and Stern (1923) found urobilinuria in each of 11 cases of progressive encephalitis. Ingestion of 100 g. of lævulose caused lævulosuria in five out of six patients, together with an increased output of urobilin. They do not believe that the probable lesion of the liver was caused by the central nervous process. Xavier (1923) carried out hepatic efficiency tests on ten cases of chronic encephalitis ; urobilinuria was present in one case. The Van den Bergh test was negative in each of five cases. Widal's hæmoclastic crisis gave a positive result in two patients, one of whom was advanced in pregnancy and the other had recently been treated with neo-salvarsan. The author concluded that there was no alteration in hepatic function.

Liver function has also been studied in 15 cases of Parkinsonism by Ottonello (1924). He found urobilinuria in six cases ; urea excretion was diminished in all 15 cases, but there was an increased urinary output of ammonia nitrogen. In ten cases the urine failed to contain glycuronates after the administration of sodium salicylate. Alimentary glycosuria occurred five times. Ottonello concluded that defective liver function was a constant feature of chronic encephalitis.

The blood-sugar in this disease has been studied by de Giacomo (1924), who found a hyperglycæmia in every one of his eight cases. Pedrinoni (1925) performed liver function tests in 16 cases of chronic encephalitis ; he found urobilinuria in 11, and in 10 cases uroerythrin was detected in the urine. The production of urea was below normal in all ; indicanuria was found in every patient. The glycogenic function was normal in nine out of 14 ; the hæmoclastic crisis test was carried out 64 times, always with a positive result ; the various components of the tests, however, were dissociated and incomplete. Halliday (1925) reports that in the acute stages of the disease the fasting level of the blood-sugar is normal ; in some cases, however, the blood-sugar curves after the ingestion of glucose indicated a delay in liver storage.

Results in our Series of 34 Cases.

Out of the very numerous tests that have been suggested as indications of hepatic efficiency we have chosen for this present investigation five—namely, examination of the urine for bile-salts and pigments, the hæmoclastic crisis test, Van den Bergh's reaction, the lævulose curve, and Roger's test (examination of urine for presence of glycuronates after an injection of 5 gr. of camphor).

Bile-salts and Pigments in Urine.—This investigation was carried out on 33 patients with uniformly negative results.

Hæmoclastic Crisis.—Twenty-five patients were submitted to Widal's hæmoclastic crisis test ; of these 12 gave a positive result. In nine of them the fall in the leucocyte count was 2000 or over. Eight patients gave equivocal results, and five were quite negative. In several patients a leucopenia was found at each examination ; thus, counts of 4400, 3533, and 1633 were found in F. G., R. F., and A. McG. respectively.

Van den Bergh's Reaction.—This test was carried out on 13 patients with completely negative results.

* Van den Bergh : 0. ‡ Weakly.

The Lævulose Curve.—In 30 cases examined by this test, a resting blood-sugar level above 0·13 per cent. was found in all. In 21 cases the level lay between 0·14 per cent. and 0·18 per cent., and in two cases it lay higher than 0·2 per cent. The average reading for all the cases examined was 0·158 per cent.

After the administration of lævulose (25–35 g., according to patient's weight) a rise in the curve occurred in 23. The elevation varied in degree from 0·01 per cent. to 0·06 per cent. ; and in time of appearance from 20 minutes to one hour : three cases gave a rise of 0·04 per cent. ; three cases gave a rise of 0·05 per cent.; one case gave a rise of 0·06 per cent. In the others the rise lay between 0·01 per cent. and 0·03 per cent., which may probably be considered within normal limits. Owing to the variable kidney threshold for lævulose present in normal individuals, routine examinations for lævulosuria were not made. Two patients showed absolutely no change in the blood-sugar level after the ingestion of lævulose; in five others there was actually a fall of from 0·01 per cent. to 0·02 per cent., extending over a period of from 30 minutes to two hours.

Roger's Test.—In 32 cases glycuronic acid appeared in the urine after the administration of 5 gr. of camphor. In one case only was an abnormal reaction found, no glycuronates being detected by Tollen's reaction.

The value of these various tests is still disputed, and some of them—e.g., the pigmentary reactions—though genuine tests of hepatic function, are probably gross, a positive result indicating severe damage to the liver. It is possible that Roger's test and the lævulose curve are more delicate criteria of the slighter degrees of liver defect. The value of the hæmoclastic crisis test is still debatable, and there even is some evidence to suggest that it is worthless as a liver function test.

In our present series all the cruder pigmentary tests have been uniformly negative; of the more sensitive tests, such as Roger's, 32 out of 33 gave normal responses. The lævulose curves were, in 26 cases, within the limits of normality, although every one of the 33 cases examined had a high resting sugar. Seven cases showed a rise in the blood-sugar of from 0·04 per cent. to 0·06 per cent. The results in the hæmoclastic crisis test were certainly abnormal, but it must be pointed out that a leucopenia has been found in many of our control cases after the ingestion of milk, and hence no deductions are permissible from these results. It is worthy of note, moreover, that no parallelism could be traced between those cases showing elevation of the blood-sugar curve above 0·03 per cent. and those cases with a positive hæmoclastic crisis.

Discussion.

The subjects of these biochemical investigations have been patients exhibiting various sequelæ of epidemic encephalitis. Most of them were examples of Parkinsonism, but a few cases presented psychical changes without gross organic defects. The patients varied in age from 10 years to 42, and the intervals between the acute attack and the investigation ranged from seven months to five years. The accompanying table attempts to correlate clinical data with laboratory findings. The results of these investigations have broadly indicated: (1) that there is no biochemical evidence of any gross derangement in the functions of the liver, and (2) that in many cases the resting blood-sugar is increased.

The metabolism of glucose has attracted most attention in respect to its presence in the cerebrospinal fluid in increased amounts. Although by no means a constant feature, nor yet confined to encephalitis only, nevertheless a "hyperglycorrhacie" is well known to be a frequent and striking phenomenon in both acute and chronic encephalitis. The figures obtained have never been very high, and have also been lower than the blood-sugar readings. Little attention has been given to the estimation of glucose in the blood in this disease. De Giacomo (1925) investigated this point in eight cases of Parkinsonism following encephalitis, and obtained in each case a definitely high figure; in five cases of senile paralysis agitans there was but a slight hyperglycæmia, which was inconstant in appearance.

During the acute stages of the disease, high blood-sugar readings have been recorded by Bourges, Foerster, and Moncandier (1920), and by Talheimer and Updegraff (1922). Normal results, however, were obtained by Foster (1921) and by Halliday (1925). From the estimations in our series it appears that a slight but definite increase in the amount of glucose in the fasting blood is of frequent occurrence. Thus all of our 31 cases have presented a mild hyperglycæmia. The average resting blood-sugar percentage for all cases has been 0·158 per cent. as opposed in 0·12 per cent. in our controls.

In spite of the definitely high amount of sugar in the resting blood, a lævulose meal produces as a rule no rise. Periodic estimations of the blood-sugar level after the ingestion of 30 g. of glucose produced in the majority of cases but little rise in the figure; the curve, moreover, rapidly "flattened out," and did not exhibit any striking deviation from the curves obtained in control cases. The cerebro-spinal fluid glucose after the ingestion of sugar was not estimated as a routine measure, but in one case in which repeated lumbar punctures were made at the same time as the blood was taken the two curves were seen to run parallel courses.

Although one of us in a previous paper has called attention to the presence in the urine of a Fehling-reducing substance in many cases of chronic encephalitis, in no instance in the present series has any constant glycosuria been observed. Two hypotheses have been suggested to explain the alterations in glucose metabolism in this disease; on the one hand, it has been supposed that the encephalitic virus has damaged various secretory elements in the extraneural systems—in particular, the liver parenchyma. On the other hand, a derangement of the sympathetic system has been suspected. The present investigations fail to support any conception of a visceral origin for these changes. Thus our hepatic efficiency tests, though admittedly crude and of unproved value, do not suggest any obvious liver insufficiency. This has tallied with our clinical observations. Uranalysis, blood-pressure readings, and renal function tests, though not reported here, have not given evidence of any kidney derangement. We have found, moreover, a normal utilisation of glucose by the tissues, in spite of the elevation of the initial reading.

It appears, therefore, more reasonable to regard these metabolic changes as evidence of sympathetic involvement. It is improbable that an infection of the central nervous system, so diffuse in its activity, would spare the various sympathetic "centres" which probably lie in the diencephalon and along the base of the fourth ventricle and medulla oblongata. Clinical manifestations of altered sympathetic activity may be pointed out in such symptoms as seborrhœa, hyperhidrosis, and vasomotor derangements.

Conclusions.

We have been unable to find any clinical, histological, or biochemical evidence to suggest an hepatic involvement after epidemic encephalitis. The amount of sugar in the resting blood, however, tends to lie at a slightly higher level than normal; it is suggested that this hyperglycæmia is the result of sympathetic dysfunction.

We beg to express our gratitude to the physicians of the National Hospital, upon whose patients these investigations were carried out.

THE AVOIDANCE OF PAIN AFTER TONSILLECTOMY.

By R. SCOTT STEVENSON, M.D. Edin.,
SENIOR ASSISTANT SURGEON, METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL; ASSISTANT, EAR AND THROAT DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL, LONDON.

In the following article I have endeavoured to focus attention on one point only, the avoidance of pain after tonsillectomy. It may seem a comparatively small point, but in reality it is very important, especially from the patient's point of view. Everyone recognises that the unhealthy tonsil is one of the main portals for the entrance of infection, and one of the chief breeding grounds for micro-organisms. Complete removal of septic tonsils is recommended, with justification, for a great variety of pathological conditions, including enlarged glands of the neck, chronic rheumatism, anæmia, "neuritis," heart disease of toxic origin, chorea, epilepsy, persistent conjunctivitis, goitre, and many others. Septic tonsils in adults are more common than is often supposed, and are undoubtedly the cause of many obscure toxæmias; but if such a cause is to be discovered it must be looked for. The throat must be examined with two spatulas, one holding down the tongue, and a smaller one exerting steady pressure outwards and backwards on the anterior pillar of the fauces, causing the tonsil to emerge fully into view, and, when it is septic, squeezing pus out of it.

Many adult patients—and I find, nowadays, that in private practice, though not in hospital, I have to perform tonsillectomy more frequently for adults than for children—are inclined, however, to refuse operation on account of fear; they know of friends who were laid on their backs after the operation, in pain and unable to swallow, for ten days or more; or they expect to remain in a nursing home for a fortnight or longer, and cannot spare the time. It is therefore of great importance to be able to assure a patient that the operation can be performed painlessly, or practically so, and that he should be able to leave the nursing home quite well after three or four days. I admit that I have given this subject considerably more attention since I had my own tonsils enucleated, and have been able to realise personally the difference in comfort that attention to small and almost trivial details can make.

The question of whether a tonsil should be enucleated by the guillotine or by dissection may be considered from the same point of view. Dissection under a local anæsthetic is a method I have never employed; I have heard surgeons speak of it enthusiastically, but I have never yet known a patient do so. It may be painless at the time of operation, but it is certainly not so afterwards. At one time I used the guillotine invariably, employing the Whillis-Sluder method. I now prefer dissection, but I still frequently employ the guillotine for children with enlarged (but not with flat) tonsils; and in hospital "tonsil clinics" it must inevitably be employed if one is to get through a large number of cases in the time available. The guillotine method, however, does cause bruising of the fauces, by squeezing the tonsil through the aperture of the guillotine and then manipulating it against the mandibular eminence, and sometimes a piece of the anterior pillar must be removed in order to enucleate a flat tonsil completely.

The avoidance of bruising and tearing means the avoidance of subsequent pain. In adults, therefore, I invariably dissect out the tonsils, employing a technique which I have modified from a method I first saw employed by Dr. George Cathcart, and which has also some points of resemblance with the method popularised by Mr. G. E. Waugh. By this technique a minimum amount of damage is done to the throat, and the wound soon epithelialises; there is little or no bleeding; stitching is never necessary, and ligaturing of vessels seldom so; and patients tell me that they have no pain—at the worst they may have some discomfort while swallowing during the first few hours after the operation. The technique may be criticised as being an elaboration of what ought to be quite a simple operation, and as requiring a somewhat longer anæsthesia than is necessary for other methods of enucleating tonsils; but I feel quite certain that the good results which it invariably ensures, the prevention of bleeding, and the avoidance of pain, make it well worth while.

Before the Operation.

The steps taken to avoid pain after tonsillectomy begin on the day before the operation, in order to prevent vomiting by minimising acidosis; it is seldom that my patients vomit more than once as they are recovering from the anæsthetic, and many do not vomit at all. Bicarbonate of soda is given three or four times during the day, before food, three or four teaspoonfuls being dissolved in half a pint of water. A child may be given a stick or two of barley sugar to suck. It is also wise to give the adult patient 20 to 30 gr. of ammonium bromide at night, to ensure a quiet sleep on the night before the operation. On the morning of operation a simple enema is given, and the patient is not allowed anything to eat or drink before the operation, not even a cup of tea or a glass of water. The operation should always be fixed, if at all possible, for an early hour, 8.30 or 9 A.M. An injection of atropine, 1/100th gr., is given half an hour before.

At the Operation.

The anæsthetic I prefer is open ether, given with oxygen, and the induction may be begun with nitrous oxide. The patient is placed on his back with a sandbag under the shoulders, and the head is lowered and well extended on the neck. This brings the chin, middle line of the neck, and the sternum almost in a direct line, and the trachea therefore slopes downwards towards the post-nasal space, so that blood cannot get down it. A good big side-to-side bite of the tongue is taken with the tongue clip (personally I use a towel clip), and the tongue is held forwards by the anæsthetist, a pad of gauze being placed between the under surface of the tongue and the teeth.

The jaws are held apart with an ordinary Doyen gag protected with rubber tubing or with O'Malley's gag, being careful not to catch or squeeze the lips. It is worth while taking some care over the placing of the tongue-clip and the gag, as not infrequently the only complaint of pain a patient has made has been of the pain in the tongue or the lips. The operator sits at the head of the table, and the anæsthetist stands on his left. It is a considerable convenience for *both* to have forehead lights, so that at least one light is always focused on the area of operation. Before beginning, a few drops of castor oil are dropped into each eye, to protect them in case any blood runs down.

The Operation.

With a pair of long tenaculum forceps the mucous membrane is picked up about half-way down the outer border of the tonsil, internal to the anterior pillar of the fauces, and as close as is conveniently possible to the tonsil. With a pair of long, straight, sharp-pointed scissors (those I use are 8½ inches long, and were specially made for me by Messrs. Mayer and Phelps) a cut is made into the mucous membrane which has been picked up, exposing the white capsule of the tonsil; the cut is continued first upwards towards the tongue, and then downwards towards the soft palate, round the border of the tonsil. The tonsil is then gently pulled forwards and outwards, and the cut is continued upwards again behind, separating the posterior pillar of the fauces from the tonsil. The operator must be careful merely to expose the capsule of the tonsil all round, and not to cut into it.

With a pair of Waugh's dissecting forceps a strip of gauze is introduced where the incision was begun, and pushed down and round between the tonsil and the anterior and posterior pillars, and then behind, wiping the tonsil in its capsule out of its bed. The tonsil is held at first with the other pair of forceps and then, as it comes farther out, with a volsellum. The dissection is done very gently and quite slowly; there is then little if any bleeding, and any troublesome vessel is secured at once with a pair of long artery forceps, which will stop the bleeding if left on for a minute or two. When the tonsil is free except for its lingual prolongation, this is clamped across with a pair of Birkett's artery forceps, and then cut off with blunt-pointed scissors; the artery forceps are left on for a minute or two to prevent any bleeding. A piece of gauze is then squeezed out of turpentine (as suggested to me—though it is an old-fashioned styptic—by Mr. Harold Kisch), packed into a tonsil bed, and held firmly there for a short time; this acts not only as a hæmostatic, but as an antiseptic, and lessens sloughing afterwards. A pad of dry gauze or cotton-wool is left in the tonsil bed, while the other tonsil is being enucleated in the same way.

When the tonsil is gently dissected out in this manner there should not be any bleeding to trouble about. I no longer apply ligatures, as I found that ligatures in the tonsil bed caused a good deal of discomfort to the patient afterwards. A few minutes devoted to waiting until bleeding has stopped, after securing the bleeding point or points with long artery forceps, will obviate the necessity for any ligatures, although I always have linen thread ligatures ready on my instrument table in case of unexpected trouble. The mucous membrane is cut all round close to the tonsil so as to preserve as much mucous membrane as one can, and to leave as small a wound as possible; instead of the wound being left gaping the mucous membrane forms a rounded border to it, and from its edge epithelialisation over the surface of the tonsil bed soon takes place, without any contraction.

After both tonsils have been removed, the throat, mouth, and tongue are cleansed of blood with warm saline solution, and any blood clot removed from the post-nasal space. A last careful inspection is made of the tonsil beds, to make sure that no bleeding point has been overlooked, before the patient is put back to bed.

After the Operation.

When the patient begins to come round I give him a hypodermic injection of heroin, $\frac{1}{6}$ gr., or omnopon, $\frac{1}{4}$ gr.; a child is given aspirin 10 gr. and potassium bromide 10 gr. per rectum or by the mouth. This gets him comfortably through the greater part of the day. When he has recovered from the effects of this, in the early afternoon, I spray the throat and all round the mouth with glycothymoline and warm water, half and half. I also give the patient an aspirin "throat bath," as Dr. Georges Portmann calls it: 10 gr. of aspirin powder is flung on the surface of half a tumbler of warm water, and before the aspirin has begun to dissolve it is held in the throat, first on one side and then on the other, as if the patient were going to gargle, but without gargling, which would hurt the throat. The aspirin powder thus gets right into the tonsil beds, where it has a very soothing effect. The patient should maintain complete silence. If he must speak at all he should speak in a whisper only, so that the sides of the fauces are not brought into play.

At tea-time, and again later in the evening, the patient may have some ice cream, or if he prefers he may drink some lemon-water or barley-water; but for the first 24 hours he should not drink very much, as swallowing may be uncomfortable. The glycothymoline sprays are continued every hour or two, the aspirin throat baths three or four times daily. At night the patient may be given aspirin, 10 gr., with potassium or ammonium bromide, 10 gr.; but he often settles down to sleep without any sedative.

Having got the patient comfortably through the first 24 hours he usually complains very little, if at all, of discomfort afterwards. He must keep as silent as possible for the next two days, speaking only in a whisper. The glycothymoline sprays and the aspirin throat baths are continued regularly every few hours as long as he is in the nursing home. An aspirin throat bath, or, as time goes on, an aspirin gargle should always be given immediately before a meal, and the food can then be swallowed without discomfort. On the second day the food should consist of bread and milk, custards, junkets, ice cream, jellies, tinned pears (which are the most easily swallowed fruit), and he may have barley-water and similar drinks. Milk must not be given, as it gets sticky and uncomfortable in the throat.

On the third day he may have, in addition, some fish or chicken. This should not, however, be pounded up into so-called fish or chicken creams; when prepared in this manner little particles get into the tonsil beds and cause considerable irritation. The patient should get out of bed on the third day, and may also have bread and butter, tea, or fruit. On the fourth day he should be able to eat ordinary food and drink ordinary drinks. He should be able to go home on that day or the next, and should begin to use his voice in the ordinary way, but without tiring it. Singers should begin to practise again at once, to assist in preventing any contraction of the pillars of the fauces.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF DERMATOLOGY AND STUDY OF DISEASE IN CHILDREN.

A combined meeting of these Sections was held on Dec. 17th, Dr. J. H. Sequeira, President of the Section of Dermatology, being in the chair, when Dr. A. M. H. Gray opened a discussion on the

Ætiology and Treatment of Infantile Eczema.

He confined himself to those varieties of eczema which attacked the face, dividing them into three classes: (1) those starting on the cheek or forehead, (2) those starting on the scalp, (3) those occurring in association with a general eczema starting on the body. In the first class an intensely itchy patch was usually followed by urticarial or erythematous lesions, not resembling bacterial infection. The prominent parts of the face suffered more than the hollows, suggesting that friction played an important part. Most of the infants were breast-fed, fat, and healthy looking. The second type often followed the rubbing of scurfy patches, and the face, when involved, usually broke out suddenly, suggesting a sudden breaking down of skin resistance rather than a spreading local infection. The type of the eruptions seemed much the same in all groups, and the clinical features depended more on the nutrition of the patient and the stage of the disease than on its place of origin.

The Underlying Diathesis.—In 40 cases of eczema seen at Great Ormond-street, 24 were of type (1), and of these ten subsequently developed asthma or recurring bronchitis; eight were of type (2) and six of type (3), and in these no chest trouble was reported. Thus it seemed that the primary facial cases had some specialised form of hypersensitiveness which was not present in the others which had only that form of acquired hypersensitiveness met with in adult eczema. The figures also supported the view that most scalp cases were infective or "seborrhœic." Five of the facial cases gave some history of recurrent rash, but always on the cheek, and there was no flexural eczema. Possibly that would develop later, as a large number of adults suffering from this gave histories of infantile facial eczema and asthma. Cyclical vomiting and hay fever had also been associated with these conditions, and the speaker was convinced that infantile eczema was one expression of an underlying diathesis which did not cease when the facial eruption got well.

Death in Eczema.—Five of the 40 children had died, one from encephalitis lethargica in later life, the others all in infancy from epidemic diarrhœa, empyema following multiple boils, and convulsions. The latter was in a scalp case and was the only one that raised the question of "eczema death."

Exciting Cause.—Some definite cause could usually be found for the primary eruption; in the scalp cases a bacterial infection was the starting-point but the facial cases were less easy to account for. Protein sensitiveness and digestive disturbance were the two theories. Most cases occurred in breast-fed children, so any protein-irritant must come from the mother's milk, but cutaneous tests with human milk had been extraordinarily inconclusive. It might be that the offending protein had been ingested by the mother and was not necessarily present at the time of testing. Several observers had found a tendency in eczema patients of all ages to give positive cuti-reactions to two, three, or more proteins, which suggested that the hypersensitiveness was not specific in infantile facial eczema. Recently certain observers had thought that different clinical types of eczema could be associated with indigestion of sugar, starch, and fat respectively. Nevertheless, as Towle and Talbot had pointed out, so many infants with indigestion of fats and sugars presented no skin lesion that there must still be some underlying condition. A large number of cases showed symptoms of over-feeding and improved considerably when the quantity of food was reduced. It seemed probable that indigestion might cause flushing and itching of the face and that the subsequent rubbing would produce in the child with a diathesis the chain of symptoms included in the primary face type.

Treatment.—The main point was to stop friction, and this could only be partially done by restraint. Change of temperature was the most potent cause of itching and should be avoided as far as possible. In non-septic cases zinc paste formed the best basis; in septic cases starch and boric acid or flavine poultices. Crude coal-tar was far the best anti-pruritic, and could be used on a face-mask, 3 per cent. coal-tar in Lassar's paste, with good results. No definite improvement followed the use of drugs, though bromide was sometimes useful, and reduction in the feeds was the only dietetic measure necessary. In early scalp cases sulphur and salicylic ointment was valuable.

The Problem of Idiosyncrasy.

Dr. H. C. **CAMERON** limited his remarks to the problem of what underlay the idiosyncrasy of particular infants to produce their tendency to eczema. How were we to explain the regularity with which an attack of measles would clear the skin absolutely and instantly of eczema? the curious association between vaccination and eczema? the risk of implanting a generalised vaccinia in an eczematous patch? He had seen one eczematous child who took chicken-pox perfectly normally. The "eczema death" might be septicæmic or due to interference with the respiratory function of the skin by the excessive use of ointments and bandages. Most of the fatal cases died with hyperpyrexia.

On the whole, the eczematous child was one who readily retained water in the tissues; it put on weight very fast and appeared very fit with a high colour, but was really an atrophic infant with the atrophy masked by the water, which might suddenly be turned out with great loss of weight. Judged by what they could do these children were not healthy. Eczema might be put into two groups: (1) that occurring in the very young, thin baby, a generalised form, and (2) that occurring in the older, fat child, on the cheeks. By fattening the first class and making the second thin the eczema would be cleared up. Many eczematous babies were spasmophiliac with a low calcium content in the blood and a tendency especially to tetany and laryngismus stridulus, and even when there were no gross manifestations the "latent signs" could very often be found in the eczematous baby. There were three conditions in which sudden inexplicable death might occur in the young child—eczema, spasmophilia, and status lymphaticus. Status lymphaticus was the post-mortem equivalent of the clinically hypolabile child, and these children had often had eczema during life. If such a child died a slow lingering death with dehydration there would be no trace of lymphoid hyperplasia post mortem. The eczematous diathesis of Czerny was the clinical analogue of status lymphaticus. In older children there were two diatheses (and in both a history of infantile eczema was often found). One was the type of child with a high lymph content in the body, an ill-defined margin to the hairy scalp, and an inveterate tendency to impetigo and chronic mucous catarrh of the lung and bowel; if there was a secondary infection with tuberculosis, as often happened, this type became the "scrofulous child." Czerny had written volumes on the ill-effect of milk in such children. The second was the intellectual, meagre, thin child, exhausting itself by the energy it put into everything, suffering from vasomotor troubles, pallor, prostration, and abdominal discomfort passing into cyclical vomiting. This child's condition was improved by cutting out milk-fat; on a high fat content in the diet they did badly and got acetonæmia, smelly breath, furred tongue, and constipation. There seemed to be some connexion between eczema and a milk diet; if the eczematous infant of 7–8 months were put on to a mixed diet with the minimum of milk it was much improved. The "diaper rash" was due to ammoniacal urine and could be put right by large doses of alkalies. Finkelstein had tried the substitution of his albumin milk, a high concentration of casein with reduction of whey and salt, and had been successful with the fat, watery infant but not with the thin type. In spite of the importance of breast-feeding, supplementary or mixed feeding was the right treatment for eczema.

Discussion.

Dr. H. G. **ADAMSON** defined infantile eczema as an eruption starting on the scalp, both cheeks and forehead, avoiding the orbits, nose, and mouth with a characteristic mask-like distribution. Usually, sooner or later, it involved the outer surfaces of the forearms and legs and sometimes the trunk. It consisted of circumscribed red areas covered with minute weeping points. The whole thickness of the skin was swollen to two or three times its normal. There was intense itching, which aggravated the condition. With careful protection from irritation it subsided and might never recur. If not cured in infancy it might last into childhood or adult life. A small percentage of uncured cases developed asthma in conjunction with the chronic eczema of childhood, but cured cases did not. Pathologically, it was a catarrhal inflammation characterised by serous exudation into the whole thickness of the skin. His experience was that it was quite independent of any digestive disturbance or food idiosyncrasy and was never influenced by dietetic measures. He inclined to the view that external irritants were the sole factor. It started on the parts exposed to changes of temperature, imperfect drying, and contact with the perspiring skin of the mother. Sudden change of temperature would produce flushing, and the irritation would lead to a dermatitis and finally an eczema. When the skin had become eczematised it became hypersensitive in other parts. Ninety-five per cent. of Dr. Arthur Hall's cases began in winter. Scalp cases always followed on scurf. The only fact against a purely external ætiology was the occasional association of eczema and asthma, but eczema might attack only one child in a family, or one of twins, and could be cured only by external treatment. Sudden death was very rare and probably due to chill, as in burns.

Prof. F. S. **LANGMEAD** said that the term "eczema" included many conditions—traumatic lesions, lesions due to heat, cold and vascular disturbance, and diseases of the nerves. It was a satisfying word, but if translated into English as "a weeping" or a sub-acute catarrhal dermatitis would be less satisfying and less likely to interfere with progress in discovering its cause. Irritants causing it included soap, wind, heat, scratching, &c.; excretions, stools, and urine: discharges; bacterial infections and irritations from within, sweat, and possibly blood. The eczema beginning about the buttocks of small babies was due to irritant excretions, especially ammoniacal fæces, and should not be treated purely as an external condition. These children took carbohydrate badly and the stool could be made alkaline by giving excess of protein; this was one of the best uses of a whole milk diet. Another type was the facial eczema, spreading over the body, in the well-nourished child with the full-moon face. It was in these that the sudden death occasionally happened. Probably there was some underlying constitutional factor in this class. A third group was associated with a protein idiopathy and the protein reactions of these should be explored. Epileptic convulsions might be heralded by a patch of eczema. In treatment something could be done with alkalies and a great deal with calcium lactate, especially if combined with parathyroid.

Dr. J. M. H. **MACLEOD** said that eczema was not a disease but a type of reaction; in the infant it was pure and more easily studied than in the adult. It was a local condition produced by scratching and rubbing. Temperature was an important factor; the majority of cases occurred in winter and yet gastro-intestinal disturbances were much commoner in the summer. He had never known it definitely produced by diet. It was extremely rare on the buttocks, which were subject rather to a papular urticaria or streptococcal infection. As soon as the local reaction had been produced the skin became hypersensitive all over and reacted more readily to minor irritants. The line to take was to concentrate on avoiding things that made the child scratch.

Dr. G. H. **LANCASHIRE** said that the majority of cases were simply the expression of a skin sensitive to external irritation, which was the only factor common to all cases. When the child was again exposed the eczema reappeared. In many cases the skin was in a neglected condition and must be cleansed first of all with starch-boric poultices, &c. Coal-tar was most useful; he preferred a 5–6 per cent. preparation with starch, vaseline, and zinc oxide. Much depended on the quality of the coal-tar. Death might be due to injudicious dressing with cold evaporating lotions.

Dr. H. **HALDIN-DAVIS** said that injudicious feeding might lead to scurfy lesions and spots, which would get better when the diet was put right, but the eczema with which dermatologists had to deal was a much more severe thing and could not be treated by diet or medicine. Protection and antipruritic measures were the sheet-anchor of treatment. We did not yet know enough to say what the constitutional defect was that underlay it. He had found that in some cases there was excess of sugar in the blood, and that the blood-sugar curve after a glucose meal showed a "sugar lag."

Dr. J. **MURRAY BLIGH** said that there was a local belief in Lancashire that if you got rid of the eczema too quickly the child died. There seemed to be something in this idea; pneumonia had some part in most of the fatalities. He had never seen eczema of the buttocks. The worst cases did not occur among the poor. For treatment a good nurse who could keep olive oil constantly applied to the whole body was the first essential. Three layers of butter muslin saturated with the best oil obtainable should be kept on the child and chloretone given to keep it quiet. Alkalies should be given as a routine because the children always developed another non-eczematous rash on the buttock. By this means the condition could be cured in about six weeks without change of diet. He was not satisfied that taking the baby off the breast had ever helped.

Mr. **FRANK COKE** said that he had obtained a history of eczema in 18 per cent. of his cases of asthma. Of 1000 cases, 225 were sensitive to food proteins, and in this group 37 per cent. had had eczema. He thought that wheat-sensitiveness played a large part. Eczema could be cured by a diet free from substances to which the patient was sensitive. On the face it was often due to sleeping on a feather pillow. Manganese and calcium cleared it up and kept it cleared.

Dr. S. E. **DORE** said that the seborrhœic type might be due to direct infection from the mother brushing her hair over the child. This could be cured locally. Thyroid was beneficial in some cases. He would divide eczema into (1) simple or traumatic, due to the infant's own secretions, and (2) seborrhœic—a very large percentage.

Dr. M. S. **THOMSON** said that the insomnia and exhaustion resulting from eczema upset the digestion, and the eczema could not then be cured until this was attended to. Hypnotics might be given more; chloral and potassium bromide was very useful. He did not see how the irritation theory could explain the sudden acute eczema in flexures. He had not seen cyclical vomiting associated with eczema, but he had with lichen urticatus.

HUNTERIAN SOCIETY.

THE second dinner meeting of the Hunterian Society was held on Dec. 14th at Simpson's Restaurant, with Dr. **HOWARD HUMPHRIS**, the President, in the chair. After dinner Dr. **CAMPBELL MCCLURE** opened a discussion on

INDIGESTION.

He said he would define indigestion, for the purpose of these remarks, as symptoms more or less connected with the upper abdomen and due to disorders of the stomach and intestines. Good functioning depended on two things, motility and secretion; but the stomach and bowels could either move too fast or too slowly and their secretions could be in excess or deficient, and all indigestion was due to one or other of these causes. The commonest initial symptoms were nausea, and pain varying between trivial and acute, in the upper abdomen. Pain in the epigastrium did not necessarily connote a severe lesion, but nevertheless called for careful observation, since there was a tendency for pains seated in remote parts of the abdomen to be referred to the epigastric region. Pain caused by pressure on the pylorus was referred to the middle line, slightly to the right, near the xiphisternum; that of gall-stones to the region of the ninth rib; and that of appendicitis to McBurney's point. A symptom of duodenal ulcer was severe gastric pain, and bad stomach-ache was also one of the signs of appendicitis, cervicitis uteri, and (in children) phimosis.

Difficulties of Diagnosis.

Apparent indigestion might, therefore, have nothing to do with the stomach, and the real trouble was often extremely hard to diagnose. Even after a close clinical examination the physician had to seek the help of the radiologist and the chemist, and even these experts might not be much more accurate than the clinician. Since the symptoms of pyloric and gastric cancer could both be produced by minor conditions, the necessity for close observation and reasoning was obvious. Many physicians tended nowadays to rely far too much on aids to diagnosis and did not think enough for themselves. Incredible though it might seem, there were still practitioners who left low corsets and underclothes in place when they examined an indigestion patient, and he had recently had three patients sent to him for indigestion, one of whom had an abdominal aneurysm and two acute appendicitis. These were bad examples of faulty examination. Moreover, X rays could rarely tell the clinician more about a case of indigestion than he knew himself, and for some radiologists the barium shadow had a fatal fascination. They would follow the advancing meal carefully down into the intestines and neglect the empty parts that it had left, and sometimes report free from organic disease a patient who suffered from functional dilatation of the stomach and duodenum and from pyloric spasm, whose cardia could be found by percussion right up to the fifth interspace well after the meal and who had been suffering from severe pain and tachycardia. Surgical interference would be disastrous to cases of this kind, and it was quite wrong to say that the physician cannot diagnose them.

Chronic Dyspepsia and the Long Stomach.

Graver forms of indigestion were due to gross lesions. Gastric ulcer, for instance, was a serious and painful condition that sometimes led to deformity such as the hour-glass stomach, and often called for surgical interference. In the many cases where the trouble came on without warning it was obvious that some factor was at work beyond mere irritation of the mucous membranes by unsuitable food. One man could eat and drink his fill for a long lifetime, another suffered from dyspepsia as a youth and died early; one would break down gastrically from worry and another would escape. In his opinion many of these cases suffered from a long stomach and a redundant colon from the day they were born. A long muscle lost tone more easily than a short one, and a long stomach, although it gave no trouble under good conditions, lost its tone directly the system encountered strain. Dyspeptics were nearly always deficient in calcium and their vitality was low; they were easily exhausted and fell ready victims to infection, which had a severe and rapid effect on the alimentary system and was often the cause of ulcers. This type of constitution was badly equipped from the start and when it came under stress the sympathetic system was liable to get out of hand. This lack of nervous control might depend on a lack of endocrine balance. The trouble was sometimes a failure to assimilate certain substances and sometimes a failure to eliminate others. The bulk of the treatment must be medical and not surgical. Admittedly gross lesions should be handed over to the surgeon, but after the operation they should be returned to the physician so that he could correct the remaining faults and obviate the danger of a relapse.

The Surgeon's Part in Diagnosis.

Mr. H. W. Carson, in opening the discussion from the surgical side, said that he was cheered by Dr. McClure's ready admission that surgery had a definite place in the treatment of indigestion. When he first went to St. Bartholomew's Hospital the number of abdominal operations performed in a year was not more than 30, and none of these had as its object the cure of indigestion. In his last year the figure was 96, of which only nine were for other complaints. The mortality at first was 70 per cent., and it spoke highly for the courage of the surgeons that they carried on in the face of this tremendous mortality until they reached the firm ground on which they now stood.

The surgeon was not a mere carpenter, diagnosis was an important part of his work. His power had been enormously increased by the fortunate advent of radiology and biochemistry soon after he began to deal with the problem of indigestion. It was now possible to say fairly accurately in any given case what had happened, but our knowledge about causation was still almost negligible. The nose, teeth, tonsils, and other potential foci of sepsis had long been suspect, but a more recent object of suspicion was food. There was no doubt that indigestion was on the increase, and it was very probable that the cause was the present faulty method of preserving food. Hardly any food escaped manipulation in some way; eggs were always suspect and milk was known to be very dangerous. Unfortunately, almost any attempt to improve the milk-supply immediately became the subject of acute political controversy and was blocked at the outset.

The most important kind of indigestion from the surgeon's point of view was that caused by gastric and duodenal ulcers. If it were true that the surgeon had no part in the treatment of any but chronic and recurring cases, the physician must claim the power of curing these ulcers, but the hospitals were packed with dyspeptics who had refused to get well and had been "thrown to the lions" for them to do their best. Duodenal ulcer was now treated by gastro-jejunostomy, often with appendicectomy and the removal of any causes of sepsis. 85 per cent. were cured, but the remainder became definitely worse, as some types of duodenal ulcer persisted in spite of gastro-jejunostomy. It was time, he thought, to ask whether the present method had not better be replaced by duodenectomy, which had a mortality of 10 per cent. but gave a positive result in the remainder.

Operations for gastric ulcer tended to become more and more radical. Results had been very poor except when the ulcer had been separated close to the pylorus, and the question arose whether gastric ulcer was not the first stage of a potential gastric cancer. The bulk of the evidence was certainly against this theory, but it underlay most of the partial gastrectomies of to-day. Whether the policy was justified only time could show. It was wrong to regard gastric and duodenal ulcers as fortuitous conditions, to be treated as well as possible. They were stages in a long course of toxæmia, which was not necessarily ended by operation, and they still required long and careful treatment after they left the surgeon's hands. It had been once believed that brain workers were especially liable to angina pectoris, but they were now known to suffer chiefly from duodenal ulcer. It was highly probable that many diagnoses of angina pectoris had been wrong, and that the pain felt near the heart was referred from the duodenum. Many physicians maintained that gall-stones were a medical complaint and could be cured by medical treatment. This belief was quite unjustified, for only surgery could remove them. It was, moreover, highly dangerous to delay the operation, as many cases showed serious complications. The difficulty lay in diagnosis, and none of the promised tests had given more than 15 per cent. of results. It was not possible to attempt a radical cure in more than 20 per cent. of cases of cancer of the stomach or 40 per cent. in cancer of the colon. Nearly all the cases that came to him had advanced growths in the stomach or obstruction of the colon, and this was because the early signs of this condition were not known, or at any rate not taught. The diagnosis was not difficult, and the fact that they escaped diagnosis was simply due to ignorance. One of the pitfalls of surgery was the right-sided abdominal pain. The origin was nearly always obscure and the surgical results disappointing. In spite of the surgeon's definite knowledge that appendicitis pain was always referred to the epigastrium, a pain in the right iliac fossa always seemed to attract him irresistibly to the appendix. Tenderness at the right iliac fossa was a reliable sign, but not pain. Diagnosis of appendicitis should never be made until the patient had had a severe attack, and certainly not on the right iliac fossa pains alone. In visceroptosis the scope of surgery was becoming more and more confined. The stomachs of many healthy people came below the umbilicus and their colons below the pelvic brim, and many had been made invalids by indiscriminate fixation. Every organ must have latitude, and it was better to cut loose structures that were normally fixed than to fix structures that were normally loose.

The Vicious Circle of Fear.

Dr. H. Crichton-Miller spoke of the vicious circle of fear and its effect on dyspepsia. When there was a possibility of grave and secret conditions the patient frequently gave way to great psychic exaggerations, and before we assessed the symptoms we should discount those that can be removed by reassurance and reason. A great many patients feared heart disease and a great many insomnia, which might come from visceral pains, heart pains, or nightmare. He protested against the habit of giving hot milk to dyspeptic patients for insomnia. They were totally unable to digest it, and inevitably woke up with pain due to fermentation and distension. Fear of the return of pain or hæmatemesis prevented us both from digesting and from seeing straight, and thus established the vicious circle. Any shock suspended the gastric processes, and could also be interpreted in terms of fear. It brought the mechanism of the adrenal into play and threw out the balance of the sympathetic and parasympathetic systems and affected either the secretory or the motor functions of the stomach. Atonicity did not depend upon any particular organ, and could only be remedied by patience. The mechanism by which fear generated wind was that the prolonged suspense caused prolonged inhibition of the adrenal secretion and therefore a vagotonic condition. During that time dilatation and fermentation were taking place. When the effort was over a sympathetico-tonic reaction occurred which compressed all the unstriped muscles and expelled the wind. Everything that made for emotional poise promoted good digestion, and all psychological methods had their value; sometimes mere reassurance was enough to break the vicious circle. The speaker deprecated the practice of dieting the dyspeptic as though he were a diabetic or a nephritic, and recommended that the patient should be encouraged to think for himself and help to work out his own dietary scheme. No group of diseases was so susceptible to "spiritual" healing as the dyspeptic group. Much quack healing flourished because a patient would give up self-pity in exchange for self-importance, which was stimulated by ceremonial and elaborate treatment, but this principle was thoroughly unsound.

Discussion.

Dr. A. C. **JORDAN** mentioned the alimentary health of certain Indian hill tribes and indicted as the cause of indigestion civilisation and the introduction of sugar and manipulated foods. That the colon especially had suffered much from highly refined cereals was shown by X rays. Chronic neuritis was one of the sequelæ of chronic dyspepsia.

Dr. D. M. **BARCROFT** pleaded for some system of adequate treatment. Alkalies were mere palliatives; the patient was probably not secreting the right kind of fluid in the stomach, but the practitioner did not know when to supply diastase, pepsin, or acid. The last-named often gravely increased the symptoms. He recommended suitable exercise and general hygiene to raise the tone.

Dr. E. **YOUNG** stated that in his experience nausea was a very unusual symptom. He did not agree that a gall-stone patient should be immediately sent to the surgeon; if he were free from symptoms after medical treatment he should not be subjected to the risk of operation. The large quantities of undigested starch often found in the fæces of dyspeptics showed the prevalence of dietetic error. Hot water and bicarbonate of soda were a better night-cap than milk.

Dr. **McCLURE** pointed out, in reply to Dr. Crichton-Miller, that fear was first felt in the epigastrium and that flatulence and dilatation of the stomach were its early signs; the first thing to do, therefore, was to get the stomach right. Psychotherapy was as valuable for correcting misinterpretation of symptoms as it was in definite mental disturbance.

LONDON ASSOCIATION OF MEDICAL WOMEN'S FEDERATION.

A MEETING of this Association was held on Dec. 8th at the house of the British Medical Association, Dr. **CHRISTINE MURRELL**, the President, being in the chair, when Dr. **MARJORIE BLANDY** read the paper on

Recognition of Early Nervous Disease,

which appeared in full in the last issue of THE LANCET.

Dr. **HELEN BOYLE** deplored the attempt to segregate into different hospitals cases of organic nervous disease and those of early mental disorder. The nervous system could not be split up; it should be regarded as a whole, since the separation of neurological and psychological factors could not in any case be attained. She was convinced that every mental hospital contained many cases suffering from encephalitis not necessarily encephalitis lethargica, but the form which might follow influenza or toxic disease.

Dr. **ELEANOR LOWRY** suggested that those cases with subjective olfactory symptoms should have the antra transilluminated to exclude local disease.

Dr. **IRENE YATES** spoke of the difficulty in diagnosing early disseminated sclerosis. Plantar response was difficult to obtain in the out-patient department.

In reply, Dr. **BLANDY** said that a true ankle clonus was pathognomonic of nervous disease, and if that were obtained it mattered less about the plantar response. She always contrived to warm the patient's feet by some means before testing their plantar response.

Dr. **ELEANOR SCARBOROUGH** read a paper on the influence of

Thyroid Feeding on Chronic Morphine Poisoning,

in which she described experiments on albino rats designed: (1) to combine thyroid feeding with chronic morphine poisoning, and to compare the susceptibility of rats to morphine with that of rats under the same doses of morphine without thyroid feeding. (2) To compare, during life, the influence of morphine, with and without thyroid feeding on the behaviour, body-weight, and temperature of the rats, and on the condition of the skin appendages; also, post mortem to compare the weights of certain organs and the structure of the thyroid glands. (3) To examine these results in relation to the various hypotheses which have been put forward to explain the relation between the activities of the thyroid gland and morphine poisoning.

She described the experiments in detail and gave the following summary of results obtained: (1) Chronic morphine poisoning when associated with thyroid feeding is not accompanied by any accentuation of the depressant action of morphine on the central nervous system, but rather by an increase in the signs of excitement of the cord. (2) The metabolic effects produced by combined morphine poisoning and thyroid feeding are more marked than those produced by either drug alone, and resemble the effects of pronounced hyperthyroidism. (3) The weights of organs concerned in metabolism are low in chronic morphine poisoning. The combination of chronic morphine poisoning with thyroid feeding tends to check the hypertrophy of these organs which otherwise accompanies thyroid feeding. (4) Chronic morphine poisoning is not associated with any change in the structure of the thyroid gland.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

A MEETING of this Society was held on Dec. 3rd, Mr. H. J. **WALKER**, the President, in the chair, when Mr. **HAROLD F. SEYMOUR** read a paper on

Some Recent Methods of Investigating the Patency of the Fallopian Tubes in Sterility.

Mr. Seymour said that it was only within the last two or three years that a technique had been worked out which satisfactorily showed whether the tubes were blocked or not. After mentioning the various contra-indications, he described these methods. (1) That of Dr. Rubin, of New York: The injection of carbon dioxide gas through a uterine cannula, the pressure of the gas being indicated by a manometer. The apparatus was fully described and shown. The advantage of carbon dioxide over air was that the former was absorbed so much more rapidly and consequently it was more comfortable from the patient's point of view. Mr. Seymour commended the water displacement meter used by Rubin as it allowed the gas to flow very gently. (2) Mr. Victor Bonney's simple method of using air was referred to. (3) Demonstrations given to the speaker by Mr. Sidney Forsdike at the Soho Hospital for Women were described—the method of injecting air through a hollow uterine dilator. By any of these means, Mr. Seymour said, it was an easy clinical test to determine if there was a free passage through the tubes or not, a test which had now become a recognised gynæcological procedure. That insufflation of the tubes had a therapeutic effect, as well as a diagnostic side, was illustrated by one of Mr. Seymour's cases. A woman, of 32, married for three years, having had no children, desired a child and sought advice. She suffered from dysmenorrhœa and had retroflexion of the uterus. A round ligament shortening operation was done curing the retroflexion and the dysmenorrhœa. A year after the operation, as she had not become pregnant, her tubes were tested and the gas did not run away at 100 mm. pressure as it did in patent tubes, but mounted to between 150 mm. and 160 mm. before it began to run off, which showed a partial block. This patient has now a healthy child, having become pregnant immediately subsequent to the gas inflation. Some of Rubin's figures were given, further illustrating this therapeutic effect.

When the tubes were shown to be blocked the next procedure was to localise the block in collaboration with the radiologist. The methods employed were as follows: (1) Injections of lipiodol, as performed by Mr. Forsdike. Lantern slides of eight cases were shown illustrating this method. (2) Injections of barium sulphate emulsion into the body of the uterus. Mr. Seymour preferred Rubin's apparatus for diagnosing the block and Forsdike's lipiodol method for locating the position of the block.

Mr. Seymour then read a short paper on the possibilities of

Endoscopy of the Uterus.

and described his own hysteroscope. He said that for some months he had been experimenting with various means of examining the cavity of the uterus endoscopically under anæsthesia after dilating the cervix. A hysteroscope, made after the style of Chevalier Jackson's bronchoscope, with two suction tubes and the light at the distal end, had given very good results. The suction tubes rapidly removed any blood and mucus which obscured the view. A Mennell's electric vacuum pump was used for suction and the instrument was made in two sizes, one with a bore of 6 mm. and the other with a bore of 9 mm., the length of the tube being 28 cm. With a special pair of forceps a snipping of any growth seen could be removed for microscopic examination.

Mr. Seymour considered that endoscopy of the uterus was going to be useful as an aid to diagnosis of the various kinds of endometritis and to differentiate between a submucous fibromyoma and a carcinoma. It was easy to see a polypus up in the fundus and the opening of the tubes could be viewed. Diagnostic curettage was far from satisfactory, and endoscopy would, he thought, eventually supersede it.

Discussion.

Mr. H. J. McCurrich emphasised the unsatisfactory results from the point of view of diagnosis obtained by curettage as usually performed.—Dr. C. G. Whorlow expected that barium sulphate emulsion injected into the uterus would pass into the abdominal cavity and remain there as a foreign body and not be absorbed in 72 hours.—Mr. J. Griffith suggested the use of adrenalin as a hæmostatic in place of the suction apparatus.

Reply.

In reply, Mr. Seymour said that regarding the use of adrenalin for stopping the dripping of blood during an endoscopic examination of the uterus, he had tried it and found it to fail, whereas continuous suction was successful.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

A clinical meeting of this Society was held on Dec. 3rd, with Dr. James Crombie, the President, in the chair.

Exhibition of Cases and Specimens.

Mr. A. Mitchell showed a boy, aged 8, suffering from Perthes's disease of the hip-joint, with accompanying skiagrams. He pointed out the difficulties of early diagnosis of tuberculous disease of the joint and the difficulty of differentiating between tuberculous lesions and Perthes's disease. In his opinion this patient had recovered much too rapidly to have had a tuberculous lesion. He also showed a girl, aged 18, with fusion of the bodies of the fifth, sixth, and seventh cervical vertebræ with practically no impairment of the movements of the neck. In this case there was a history of a fall when aged 6 months. —Mr. William Anderson confirmed Mr. Mitchell's opinion as regards the early diagnosis of hip-joint disease.

Mr. William Anderson showed a case of diffuse carcinomatosis of the breast, where the only complaints were stiffness of the shoulder and œdema of the arm, the duration of symptoms being two weeks. There was no palpable tumour in the breast, but marked cancer en cuirasse in the lower segment. The axillary glands were markedly enlarged. Microscopic examination of a small piece of skin showed extensive infiltration of the deeper layers with carcinomatous cells. Operative treatment was not advised.

Mr. G. H. Colt showed a man, aged 68, with marked fixation of the lower jaw following removal of a recurrent tumour of the right cheek and alveolar margins. The contracture was evidently not due to any affection of the temporo-mandibular joint, but rather to adhesion of scar tissue in the cheek, which had been split at the time of operation, to the upper and lower jaws. Mr. Colt asked for suggestions as to further treatment, his own suggestion being to divide the constricting bands and to insert an epithelial graft which could be kept in place by a stent mould with the jaw half open.

Mr. Andrew Fowler showed a girl, aged 13, whose fifth metacarpal bone of the left hand had been removed intact for a possible sarcoma. A tibial graft, including periosteum, had been inserted with very little shaping, and in the space of 19 months this graft had almost assumed the shape of a metacarpal bone with a head and new "metacarpo"-phalangeal joint. The usefulness of the hand was not impaired, there being two-thirds normal flexion at the new joint, and the patient, according to her own statement, is able to play octaves on the piano. On microscopic examination the tumour was found to be an osteochondroma. A series of skiagrams illustrated the changing appearances of the graft.—Mr. Mitchell emphasised the importance in these cases of beginning active and passive movements at an early date after operation.

Dr. P. Howie showed two cases of deformities of the hands, one of brachydactyly of the ring finger of each hand, and one of megalodactyly. He also showed two patients who had been operated on for carcinoma of the stomach, a male in July, 1921, and a female in 1909. The male patient until recently had no sign of recurrence when he had a hæmorrhage from the bowel. The female patient looked very well and had no signs of recurrence.—Dr. A. G. Anderson, Dr. J. Cruickshank, Mr. F. K. Smith, and Mr. William Anderson discussed the authenticity of the pathologist's findings in these cases. Dr. Cruickshank suggested that when a patient was alive a considerable period after an operation for carcinoma of the stomach the sections of the tumour ought to be sent to at least six pathologists for confirmation.

Mr. G. S. Davidson exhibited a case illustrating one of the rarer causes of neonatal hæmorrhage. The case was one of a vaginal hæmorrhage in a 5 days old child. He indicated the points in diagnosis and postulated an explanation of the cause of the condition.—Dr. **EDWARD WALKER** asked if Mr. Davidson could explain the cause of engorgement of the breasts in the newly born.

Dr. J. **CRAIG** exhibited a boy of 6 years who had during the last 18 months shown all the manifestations of rheumatic infection—viz., carditis, arthritis, chorea, and subcutaneous nodules. In Dr. Craig's opinion subcutaneous nodules of rheumatic origin are not so rare in this part of the country as is commonly supposed, he having seen three cases during the past year.—The case was discussed by Dr. A. G. **ANDERSON**, Dr. W. **BROWN**, and Dr. H. R. **SOUPER**.

Dr. A. C. **FOWLER** showed skiagrams of a gall-bladder containing numerous stones. Definite indentation of the pyloric antrum by the gall-bladder was seen during a barium meal investigation. The case was one of unexplained diarrhœa.

Dr. J. F. **CHRISTIE** showed a man of 70 with a slowly-growing ulcer on his left ear. The duration was 9 months without active treatment. On section the report was not definitely epithelioma. The Wassermann reaction was negative. There were no enlarged cervical glands. Dr. Christie asked for suggestions as to the diagnosis.—The opinion of the meeting was in favour of epithelioma and removal of the whole ear suggested as the treatment.

Election of Officers.

The following office-bearers and members of Council have been elected for the ensuing year:—President, Dr. J. Crombie; vice-president, Dr. J. F. Christie; secretary, Dr. H. Edgar Smith; treasurer, Dr. G. Rose; editor of transactions, Mr. G. H. Colt; librarian, Dr. W. Clark Souter; recording secretary, Mr. Andrew Fowler; assistant secretary, Dr. Robert Richards; members of Council, Dr. A. G. Anderson, Mr. F. K. Smith, Dr. H. R. Souper, Dr. G. M. Duncan, Dr. P. Howie, Dr. T. Fraser, Dr. J. Ross Mackenzie, and Mr. William Anderson.

PATHOLOGICAL SOCIETY OF MANCHESTER.

AT a meeting of this Society on Dec. 9th, Prof. E. D. **TELFORD** in the chair, a discussion on

Occult Sepsis

was opened by Dr. E. M. **BROCKBANK**, who referred to the various conditions of oral sepsis which produce metastatic affections of pyrexial and apyrexial nature in almost any organ of the body and which may be of slight nature or severe enough to cause death. He paid special attention to disease at the roots of old filled or crowned teeth which can only be recognised by X ray films taken and interpreted by experts in such work. This is a most dangerous dental lesion because there is no evidence of any disease about the teeth or gums to be seen by the unaided eye. The pyrexia which accompanies such foci or occult sepsis may vary from simple septic swinging temperature to a daily rigor of 105° F. or more lasting for weeks. Removal of such teeth leads to recovery from complications even after the lapse of several months.

Mr. **BARRON J. RODWAY**, who illustrated his remarks with a number of excellent slides, spoke of the difficulty of deciding how far oral sepsis was responsible for the causation of general illnesses, but drew attention to the frequency with which cases were seen where marked improvement followed dental treatment, which, prior to this, had come to a standstill under medical treatment. He described three types of dental condition likely to lead to a general infection—the neglected mouth, where the infection was chiefly the result of swallowing contaminated saliva and food; the mouth in which insufficiently treated non-vital teeth were present, where the infection took place entirely via the bone; and the mouth in which pyorrhœa was present, where the infection took place both from the swallowing of the products of the disease and also through the periodontal membrane. Reference was made to the question of deciding when to extract and how extensive an operation to make; and a comparison was made of the prospects of a possible cure of general disease at the price of having to manage with artificial dentures which, at the worst, would enable a selected diet to be dealt with, or the almost certain prejudicial effect of the continued presence of a definite source of infection by the retention of probably only partially efficient natural teeth in an unhealthy condition.

Mr. F. **HOLT DIGGLE**, after briefly dismissing the question of sepsis in the middle-ear cleft as a site for sepsis frequently overlooked—though in his opinion more commonly associated with disorders of malnutrition than arthritis or allied conditions—then considered the question of sepsis in the faucial tonsil. He pointed out that the submerged variety of tonsil was the greatest offender, and drew attention to the anatomical arrangement of the long, narrow, tortuous crypts, and the large absorptive area of the capsular surface of the tonsil, as factors rendering the tonsils peculiarly liable to the harbouring of unsuspected sepsis. After briefly considering the experimental and clinical evidence in support of the assumption that the tonsils may be the source of a systemic infection, he considered the results to be obtained by total enucleation of the tonsils. It was pointed out that tonsillectomy performed in cases of chorea did not yield such good results as those to be obtained in cases of arthritis, and particularly in cases of acute rheumatic infections. Mr. Diggle then dealt with the diagnosis of a septic tonsil, and pointed out that swabs taken from the tonsils of apparently healthy people were never sterile. He referred to the work of Howarth and Gloyne on this subject, and considered that factors other than bacteriological examination must be taken into account. He stressed the value of squeezing the tonsil to express material from the crypts, the bleeding from the crypts after moderate pressure, the local redness of the tonsil, and particularly the narrow red streak along the anterior faucial pillar, as perhaps less obvious evidences of tonsillar infection. He further considered that before a tonsil was sacrificed in cases of systemic infection we must be reasonably sure, first, that the tonsil is diseased; secondly, that the tonsil is the only source of infection; and, lastly, that if the tonsil is infected it is the source of the general infection.

In his opinion dental sepsis should be corrected before tonsils were removed, and a complete bacteriological examination of the intestinal and genito-urinary tract as well as the coöperation of the dentist and radiographer should be essentials in the investigation of every case. The question of sepsis in the nasal accessory sinuses was very briefly considered. It was pointed out that the absence of a purulent nasal discharge did not exclude the existence of pus in one of the sinuses. Mr. Diggle stressed the value of examination of all the sinuses by means of the suction syringe in doubtful cases.

Corrigendum.—Prof. Arthur Ellis wishes it to be known that he did not take part in the discussion on Nephritis at the Section of Medicine, R.S.M., on Nov. 24th. The remarks attributed to him in our issue of Dec. 5th (p. 1168) were made by Dr. H. A. Ellis.

APPOINTMENT OF A NEW VIVISECTION INSPECTOR.—The Home Secretary is about to appoint an inspector under the Cruelty to Animals Act, 1876. The post is permanent and is pensionable in accordance with the general rules governing the grant of pensions in the Civil Service, and the appointment will be subject to a period of probation. The salary will be £800 a year, together with bonus on the scale authorised for the Civil Service and travelling allowances at the usual Civil Service rate. The inspector will be required to give his whole time to his duties, and to reside at Edinburgh for the time being. Candidates for the post who possess the scientific qualifications required for the work and are not over 50 years of age, should apply to the Private Secretary, Home Office, Whitehall, London, S.W. 1, from whom further information may be obtained. Applications should be accompanied by one or two testimonials and particulars of the candidate's qualifications, and should reach the Home Office not later than Jan. 15th, 1926.

Reviews and Notices of Books.

BIOCHEMISTRY.

Applied Biochemistry. By WITHROW MORSE, Professor of Physiological Chemistry and Toxicology, Jefferson Medical College, Philadelphia. London: W. B. Saunders Company, Ltd. Pp. 958. 32*s.* 6*d.*

Prof. Morse's book aims at covering the whole field of biochemistry, both from its physiological and pathological aspects. Physical chemistry, methods of analyses, and even recent views on the structure of the atom and matter are dealt with. The range of the author's task thus will be appreciated, and Prof. Morse has succeeded to a really remarkable extent in fulfilling it. The book opens by defining the aims of biochemistry in general and tracing out the scientific ancestry of the great American biochemists. The author proceeds to a general but thorough consideration of the structure of matter, including the electron and proton theory. The lattice structure of crystals is discussed. Physical chemistry of solutions is next dealt with and particular reference is made to hydrogen-ion concentration. This section is an excellent, clearly written account of the physical chemistry of ionisation, and the author points out its application to the acid-base problems arising in the body. Enzymes and colloids are next reviewed, after which the elementary composition of tissues is dealt with. The three succeeding chapters are taken up with the chemistry of proteins, fats, and carbohydrates, whilst the fourth is devoted to the chemistry of tissues in general. The following chapter concerns the chemistry of foods, and then digestion, absorption, and metabolism are discussed. The biochemical aspects of urine, ductless glands, and nutrition are also dealt with quite fully. Under the title of Practical Exercises on Urine and Blood a scheme for practical work is included, and in an appendix methods for the preparation of various reagents and solutions are given. After each chapter a series of selected references is included, and throughout the text appear portraits of many of the workers referred to, in many cases short biographical notes being given.

From this outline it can be understood that here is no ordinary volume. The conception of providing a complete work on so huge a subject is admirable, and the author has succeeded in conveying to the reader the idea that biochemistry is an active dynamic subject. Some minor points are open to criticism. To the English reader the renaming of proteins, fats, and carbohydrates as proteids, lipids, and glucids is distasteful. There are a few errors in the biographical notes; for example, Dr. F. G. Donnan would undoubtedly be surprised to see himself described as a professor of physiology. Some few of the illustrations are redundant. But these things amount to nothing. Prof. Morse has performed a wonderful service to biochemistry and its students, and any reader equipped with his volume could be regarded as being well armed.

Monographs of Biochemistry. Edited by R. H. A. PLIMMER, D.Sc., and Sir F. G. HOPKINS, M.A., M.B., D.Sc., F.R.S. *Hexosamines and Mucoproteins.* By P. A. LEVENE. Rockefeller Institute for Medical Research, New York. London: Longmans, Green and Co. 1925. Pp. 163. 10*s.* 6*d.*

THIS volume consists for most part of a summary of the author's own researches. Dr. Levene has performed so much pioneer work himself in this field that the excellence of the volume goes without saying, and since he has published many recent papers, it is expedient to have his results in a monograph. In the present volume the subject of hexosamines and mucoproteins is dealt with very thoroughly and the historical summaries are full and useful. One of the most interesting chapters is that dealing with the Walden inversion. This difficult subject has received little attention in the English language, and Dr. Levene's account of its importance in relation to the hexosamines forms one of the most valuable features of the book. Dr. Levene points out in his introduction that there need be no apology for writing a volume on such a specialised subject, since mucoproteins are constituents of every tissue.

SEWAGE PURIFICATION AND DISPOSAL.

Second edition. By G. BERTRAM KERSHAW, M.I.C.E. Cambridge Public Health Series. Cambridge University Press. 1925. Pp. 339. 18*s.*

THE appearance of the second edition of this useful book will be welcomed by all who are interested in the subject of sewage disposal. Much work has been done since 1915, when the first edition appeared, especially with regard to the so-called activated sludge process. The new chapter entitled Activated Sludge Processes, Sludge Digestion, contains an account of the Sheffield bio-aeration process, which it is intended to apply to the whole of the sewage of Sheffield. We regard this as an important inclusion, because we believe that Mr. John Haworth, the manager of the Sheffield works, was the first to show that sufficient oxygen for biological purposes could be introduced into the sewage by mechanical agitation without the necessity for blowing in air. Mr. Kershaw, in his capacity as engineer to the Royal Commission on Sewage Disposal, had an excellent opportunity of familiarising himself with all methods, and he has utilised that opportunity to the full.

The new edition has been brought thoroughly up to date, and we commend it to all who have to deal with sewage purification and disposal.

SKULL FRACTURES.

Roentgenologically Considered. By WILLIAM H. STEWART, M.D., Roentgenologist to the Lenox Hall and Harlem Hospitals. New York: Paul B. Hoeber. 1925. Pp. 64. $12.

IN this volume by means of a series of fine skiagrams practically every possible fracture of the skull is illustrated. Each illustration is accompanied by a short clinical account of the case and the nature of the accident from which the injury resulted. A brief chapter on rontgenographic technique indicates precisely the method adopted, but we fear the surgeon might follow its instructions implicitly without obtaining such results, unless he possessed the supreme skill which these must have required. The plates are in every instance superb, and, quite apart from their surgical value, they present a remarkable series of studies of the human skull which should be of great interest to the anthropologist. The book is magnificently produced.

PRACTICAL PHARMACOGNOSY.

By T. E. WALLIS, B.Sc. Lond., F.I.C., Ph.C., Lecturer in Botany to the Pharmaceutical Society of Great Britain. London: J. and A. Churchill. 1925. Pp. 115. 7*s.* 6*d.*

THE work of the student of medicine is now far removed from that of his predecessors, who manufactured their own drugs, this work to-day being undertaken by the manufacturing chemist. He cannot, however, altogether afford to neglect any of the links in the chain of the healing art. This book of practical pharmacognosy will make an appeal to the doctor who takes interest in drugs as well as to the student in pharmacy, to whom it is of more vital interest. Mr. H. G. Greenish, who writes a commendatory foreword, points out that, too often, the teacher of pharmacognosy is contented to lecture on the subject and to leave the student to examine the crude drugs at his leisure, without systematic instruction or guidance, with the result that he acquires but a superficial acquaintance with the drugs at his disposal. In this book the earlier portion is devoted to 18 schedules of instructions, which state fully but concisely the details of practical work for each day of the course. The descriptions are clear and free from unnecessary material. The later part is devoted to the description of 45 medicinal plants indigenous to Great Britain; this sets out their characteristics and makes their recognition easy.

The writer is to be congratulated on his book and especially on the illustrations, largely by himself and his wife, which make the volume attractive.

PREVENTIVE MEDICINE.

Second edition, revised. By MARK F. BOYD, M.D., M.S., C.P.H., Member of the Regular Field Staff, International Health Board of the Rockefeller Foundation. London: W. B. Saunders Company, Ltd. 1925. Fully illustrated. Pp. 429. 20*s*.

THIS book, the first edition of which appeared in 1920, bears impress of a somewhat different outlook on public health from that of this country. Thus the subject of meat inspection is dismissed with a few words because "in the United States but little progress in meat inspection has been made"; on the other hand, rather more attention is paid to tropical diseases, such as malaria and uncinariasis. Interest attaches to a statement that "thanks to national prohibition this disease (alcoholism) will soon be a matter of historical interest in the United States." The book has not been written for the specialist but for practitioners whose daily work is causing them more and more to require general knowledge of preventive medicine, and the perspective is good. One of the most difficult subjects to deal with in an elementary way, that of statistics, is clearly and simply discussed. The book may be recommended to medical students who to-day in certain schools have to face a separate examination in public health; they can easily supplement their knowledge by reference to English standard text-books, many of which are not presented in so simple or so readable a form. The volume is profusely illustrated; for the most part the illustrations are good, but some are not informative.

EVOLUTION AND GENETICS.

By T. H. MORGAN. Princeton: University Press. 1925. Pp. 211. 9*s*.

Prof. Morgan says: "It has been pointed out that the power to reproduce itself puts the problem of the construction of a living organism on a different footing from the construction of a complex machine out of inorganic material." It is easy to believe that a problem is likely to reproduce itself a good many times if it is written about in this way. Unfortunately, Prof. Morgan's most interesting defence of the possibility of Mendelian mutants being the origins of new species is spattered with sentences more appropriate to those mystics of biology on whom he pours so much scorn. The book is a robust statement of his belief and is framed mainly as an answer to Bateson's statement that modern genetics had thrown no light on the production of fresh species of animals and plants. It is true that no observed mutant has shown the hybrid sterility of natural species; it is equally true that most mutants which have occurred under observation would have apparently no chance of survival in the real competitive world. But it is only necessary to suppose that one or both of these things happens very occasionally, and it may well be that it is necessary for permanent establishment that a hybrid should be sterile with the original stock so that the fresh form may have a position in nature delimited from that of its progenitors. And in a general way Prof. Morgan puts forward a strong case for looking on animals and plants as compounded on a gene basis. But it is not really necessary to his argument to show that Lamarckians are wholly wrong—which, indeed, he plainly fails to do. It seems much more likely that both views are partly right.

With some reservations we can commend the book as a stimulating critique of evolution theory from a modern point of view.

THE PHYSIOLOGY OF MIND.

An Interpretation based on Biological, Morphological, Physical and Chemical Considerations. By FRANCIS X. DERCUM, A.M., M.D., Ph.D., Professor of Nervous and Mental Diseases in the Jefferson Medical College, &c. London and Philadelphia: W. B. Saunders Company. 1925. Pp. 287. 16*s*.

Prof. Dercum believes that he has solved the great problem of mind and body. This he does by a series of ingenious speculations, based upon the findings of physiology and chiefly concerning neurones, which renders unnecessary the conceptions of psychology; in fact, he says in his preface that there is an inherent objection to the term "psychology," for psychology can only be regarded as a department of brain physiology. An example will show the apparent simplicity of this point of view, which is not novel, though the author uses the latest advances in knowledge to elaborate his explanations. He points out how "the retraction of the dendrites and axones of the neurones explains the palsies and anæsthesias of hysteria" (p. 225), and then describes how Babinski showed that the anæsthesia arises because of the method of examination. So we may imagine the examiner saying, "Do you feel this?" when straightway the dendrites and axones retract and the anæsthesia comes into being. There is no doubt that every human action, thought, or emotion can, with some ingenuity, be explained by a similar postulate. But is this helpful? And is it physiology?

WELFARE WORK IN INDUSTRY.

Edited by ELEANOR T. KELLY, B.A. London: Sir Isaac Pitman. 1925. Pp. viii. + 119. 5*s*.

THIS volume has been written by members of the Institute of Industrial Workers, under the editorship of its President, Miss E. T. Kelly. It contains a concise outline of the principles and practice of welfare work in factories, and while chiefly intended for those engaged in industry, is of considerable interest to all whose work brings them into contact with cognate problems. The book is written from an idealistic standpoint, and the chapter dealing with the activities of the works' doctor demands an extremely high standard of service from this hard-worked officer. A valuable section is the appendix, containing, amongst other things, specimen record cards for medical inspection, for the categorisation of accidents, and an interesting section on industrial fatigue.

The book is a reasoned attempt to establish a philosophy which will be a guide to the student and a basis for the professional worker.

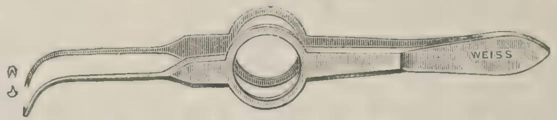
JOURNALS.

QUARTERLY JOURNAL OF EXPERIMENTAL PHYSIOLOGY. Vol. XV., Nos. 3 and 4. 1925. Pp. 201–450. 25*s*.—Among the articles appearing are the following. The Effect on the Stomach of Stimulation of the Peripheral End of the Vagus Nerve, by E. D. McCrea, B. A. McSwiney, and J. S. B. Stopford. The authors give a summary of the facts elicited by previous workers on the effects of vagal stimulation as regards (1) motor effects, (2) inhibition, (3) on the fundus and cardia, (4) on the pyloric sphincter, (5) the vasomotor phenomena, (6) on the duodenum, and (7) the relation of vagal stimulation to tonus. They discuss advantages and disadvantages of their technique, which consists of the introduction into the stomach of a balloon with an air system, or with a water system, or the water distension method, the observations being made by means of X rays. The main conclusions reached are as follows: The primary effect of stimulation of the peripheral cut end of either vagus on the stomach is dependent on the existing condition of the peripheral mechanism ("tonus"), and may be inhibitor or augmentor. The inhibitor or augmentor effect may involve both "tonus" and movement. The final effect of stimulation is to bring about augmentation of existing movement or to initiate movement. "Tonus" and contraction may vary inversely or directly.—The Effects of Fatigue and Temperature on the Adrenal Bodies of the Rat, by Swale Vincent. If white rats are exercised at room temperature in winter by means of a revolving drum made of wire netting and driven by a motor, their body temperature will fall and the chromaphil reaction of the adrenal medulla will be markedly reduced. If they are exercised at higher temperatures their body temperature will rise and the chromaphil reaction will not be reduced. At about from 18° to 20° C. the body temperature neither rises nor falls with exercise, and the chromaphil is unaffected. Considerable reduction of the temperature of the surrounding medium may, independently of exercise, cause a diminution of the chromaphil reaction if the animal's temperature becomes lowered, but this does not occur very frequently in the case of white rats. It seems, then, that the effect of exercise on the chromaphil reaction is not direct but secondary to the lowering of the animal's temperature.—The Active Principles of the Posterior Lobe of the Pituitary Body, by Walter Schlapp. Uncertainty exists as to whether the many physiological responses known to be evoked by extracts of the posterior lobe of the pituitary body are to be attributed to one or to more than one active principle. Histological and physical means have been employed. The author reviews the results already obtained and then describes his own method of preparing extracts from desiccated pituitary material. He finds that when depressor-free extracts are boiled with dilute hydrochloric acid, the oxytocic, pressor, and melanophore responses evoked by them are destroyed slowly and simultaneously. By treating depressor-free extracts with N-butyl alcohol it is possible to separate a fraction into which the greater part of the oxytocic activity has passed. By producing precipitates of lead sulphide in extracts by passage of sulphuretted hydrogen gas through suitable concentrations of lead acetate all the active principles are to some extent adsorbed. But the quantity of pressor and melanophore substance adsorbed exceeds that of oxytocic adsorbed by a significant amount. These results show that the oxytocic response on the one hand and the pressor and melanophore activities on the other must be attributed to distinct substances. The experiments, however, provide no positive evidence that the pressor and melanophore responses are due to distinct substances.—The Structure and Function of the Spleen, by John Tait and Martin F. Cashin. The authors give a full review of the literature of the subject as regards structure, the phagocytosis of particles, the reticulum, arteries, ellipsoids, veins, injection of vessels, the course of blood in the spleen, and its contractility. The spleens, chiefly of dogs and cats, were perfused by the arteries and veins with warm Ringer's fluid charged with specially prepared Indian ink particles. The authors find that the spleen is divided into segmental zones or lobes, corresponding to the branches of the arteria lienalis which enter it. These zones are at once arterial and nervous units. The scheme of subdivision of the splenic nerve corresponds to these segmental zones, and stimulation of a branch of the nerve causes only a section of the spleen to contract. Central to the cœliac ganglion (e.g., in the splanchnic nerve or in the anterior spinal roots) there is no such segmental representation in the branches proceeding to the spleen. The splenic vein is conspicuously larger than the splenic artery, that of the ox being five times the diameter of the artery. When a short section of the vein is electrically stimulated it contracts and remains in strong contraction for an hour or more, the outflow of blood being greatly impeded. When the spleen is perfused with Indian ink the particles may come to rest in four different situations: (1) in the ellipsoids, (2) in the spleen phagocytes, (3) on the ordinary reticulum, (4) on the walls of the venous sinuses. In the living animal deposition in the ellipsoids is temporary. Within three hours after intravenous injection of the ink phagocytes have begun to clear the particles from the spaces within the ellipsoids. Twenty-four hours later the ellipsoids are free. The phagocytes of the pulp retain the particles for weeks on end. At first they clear the ink off the reticulum. After a month they can be seen to have undergone a rearrangement, and some have migrated into the Malpighian corpuscles. The ellipsoids act as valves, readily allowing the blood to flow in the normal direction—i.e., from the interior to the exterior of the ellipsoid—but instantly closing against higher pressure applied to their exterior. The existence of these valves accounts for the difficulty of perfusing the spleen backwards—i.e., from vein to artery. Each ellipsoid is surrounded by a number of venous sinuses which become dilated when the venous pressure is increased.—The Appearances of Mammalian Erythrocytes under Dark-ground Illumination, by W. G. Millar. No sign of internal structure can be seen in the human erythrocyte.—Technical Points Important for the Study of the Metabolism of Rabbits, by V. Korenchevsky.—The Pancreas of Teleostean Fishes and the Source of Insulin, by Swale Vincent, E. C. Dodds, and F. Dickens.—The Sensitivity to Different Regions of the Spectrum of Individuals with Hypochromatic Vision, by H. N. Bradbrooke and H. E. Roaf.

New Inventions.

RING GRIP FORCEPS.

There is perhaps no more delicate piece of manipulation in all surgery than that required of the left hand of the ophthalmic surgeon when he picks up with his forceps a minute strand of the iris preparatory to iridectomy. The tissue to be gripped is so slight, it is so often obscured by overlying tissues or blood, and the margin of safety in the movement of the iris is so narrow that the mastery of the forceps through which the actual movement has to be made should be as perfect as is possible. For a perfect success the instrument—the forceps—should be a part of the hand of the surgeon, as much part of it as ungual appendages to his fingers. There are many excellent iris forceps in use, but they all remain an instrument in the hand—they do not become part of the hand. In the forceps, of which an illustration is here given, the customary solid side plates or bows are expanded so as to allow a ring to be cut through the flat of each side. These rings are 8 mm. in diameter inside, their edges are square and not bevelled. They are cut in the positions into which the thumb or first finger naturally falls when holding the forceps. When the forceps are taken up as in use the pads of the extremities of the thumb and index-finger fill these holes in the forceps, and at the moment that the teeth of the forceps engage the skin of the thumb and finger come into contact, so that one feels that the forceps are almost a part of the hand and that the points are just the extensions of the finger-tips. The sense of direction and security this gives is remarkable. The grip is applicable to any form of forceps.



Messrs. John Weiss and Son, Ltd., Oxford-street, London, are the makers of the instrument.

THE LANCET.

LONDON: SATURDAY, DECEMBER 26, 1925.

THE EFFICIENCY OF THE HEART.

Progress in the study of any fundamental principle in science may conveniently be divided into three stages. The enunciation and qualitative proof of the principle naturally marks the first stage. In the second greater elaboration of technique leads inevitably to a quantitative interpretation of the particular phenomenon studied. This in its turn stimulates the imagination to a still deeper and more intricate examination of the intermediary steps involved and finally to a re-examination from a quantitative point of view of the facts thus brought to light. The study of metabolism, as was pointed out by Noorden, forms an excellent illustration of progress along these lines. The qualitative period may be said to have been inaugurated by Wöhler's synthesis of urea and by his proof of the synthetic capabilities of the organism in respect to hippuric acid. The quantitative period of Voit and Pettenkofer followed, and the gross chemical principles laid down by them are now being analysed in terms, qualitative and quantitative, of intermediate metabolism.

The study of the circulation is proceeding along comparable lines. It is nearly 300 years since William Harvey made his supreme contribution to biology by showing that "it is absolutely necessary to conclude that the blood in the animal's body is impelled in a circle and is in a state of ceaseless motion; that this is the act or function which the heart performs by means of its pulse; and that it is the sole and only end of the motion and contraction of the heart." In two lectures on the efficiency of the heart and its measurement, the second of which we print in this issue, Prof. Yandell Henderson points out that by means of a method introduced by Dr. H. W. Haggard and himself it is at long last possible to measure the circulation rate in man under a variety of physiological conditions and even in cases of moderate cardiac impairment. All the methods which have been used hitherto on man, and which at the same time may lay claim to some degree of accuracy, are based on Fick's principle—namely, that if we know the difference in the oxygen contents of the arterial and venous blood coming from and going to the lungs and at the same time the oxygen consumption of the individual under examination, the ratio of the latter to the former of these two figures gives us a true measure of the cardiac output, assuming, of course, that no oxygen is utilised in the lungs themselves. An exactly analogous method has also been adopted in which the ratio of CO_2 production to arterio-venous CO_2 difference is determined. The oxygen or CO_2 content of the arterial and of the venous blood is determined from analyses of arterial and venous alveolar air respectively, the gaseous tensions so found being interpreted in terms of blood oxygen or carbon dioxide content from the oxygen or carbon dioxide dissociation curves of the blood of the person investigated. These methods are complicated, and since they require the active and intelligent coöperation of the subject under examination are entirely unsuited to clinical use. Krogh's nitrous oxide method suffers from the same drawbacks. In ethyl iodide, however, Prof. Henderson and Dr. Haggard have found a volatile substance which not only possesses a low solubility coefficient, but also has the great advantage of being destroyed in the tissues, there being thus no necessity to limit the experiment to the time of one circulation. It has been shown that the partition coefficient of this gas between air and blood is 2. Given, therefore, the amount of ethyl iodide absorbed over a given period of time and a knowledge of the content of the alveolar air in this gas, we can readily calculate the volume of blood which has passed through the lungs in that time. The method is simple, accurate, and involves no more coöperation on the part of the patient than a simple basal metabolism determination.

The chief function of the heart is to supply oxygen at a high pressure to the working tissues. That is to say, the mean capillary oxygen unsaturation of the blood must be maintained at a low level by a correspondingly rapid rate of blood flow. Clearly the first indication of circulatory failure will be a rise in the arterio-venous oxygen difference. As Prof. Henderson states in his lecture, "the arterio-venous oxygen difference is the best possible index and measure of functional efficiency of the heart." Prof. Henderson's great contribution to medicine is that he has made it possible accurately to measure this difference not only in persons under varying conditions of physiological stress, but also in patients suffering from moderate degrees of cardiac impairment. He has determined that this difference is constant at a value of 3 to 4 volumes per cent. in dogs and men of very varying size, and appears to be a fundamental mammalian "constant" comparable to that of body temperature, of hydrogen-ion concentration of the blood, and of arterial pressure. On account of this constancy in the arterio-venous oxygen difference in all vigorous mammals and of the direct proportionality between basal metabolism and body surface, it is interesting to note that the volume of the circulation also becomes a function of body surface and not of body weight. Small animals therefore have a relatively more vigorous circulation than large, and this relative increase in the circulation rate with diminution in size is conditioned not by an increase in the stroke volume of the heart, but by an increase in rate. Indeed, Prof. Henderson has shown that the output of the heart in all healthy vigorous animals during bodily rest is 1·4 to 1·8 c.cm. of blood per kilo per beat. This figure is known as the stroke index. With moderate activity there appears to be very little increase in this index, the increased blood flow being mainly determined by acceleration in the pulse-rate. In more vigorous exertion, however, the second and third reserves of the circulation are called up—namely, an increase in the arterio-venous oxygen difference and an increase in the stroke index. Of extreme interest to clinicians is the relatively enormous increase (40 to 50 per cent.) in the circulation rate occasioned in normal men by a change from the upright to the lying posture.

Prof. Henderson has accumulated a large stock of data on the circulation in health, and these figures must prove of great value as a base line from which to compute the significance of corresponding figures found in pathological states. Should the method which he now places in the hands of physiologists prove as valid 300 years hence as Harvey's immortal discovery proves to-day, his contribution will indeed be significant.

SCARLET FEVER AND THE DICK TEST.

The control of scarlet fever is still unachieved. Since the passing of the Public Health Act of 1875 hospital isolation has afforded individual patients a better chance of recovery, but it has done nothing to diminish the incidence of the disease. This was admitted quite freely at a recent meeting of the Royal Society of Medicine,[1] when Dr. M. Greenwood stated that the only hope lay in immunisation, and there was none to disagree with him. Fortunately the publication of the work of the Dicks in 1924 has opened up an entirely new prospect, and the three papers on the Dick test which appear in our present issue will serve to illustrate what has already been done and what still remains to do. The first thing needful is to know who are and who are not susceptible to infection. We know broadly, write Dr. R. A. O'Brien and Dr. C. C. Okell, that a negative response to the Dick test indicates a high degree of non-susceptibility, but it is not so clear that a positive reactor may not possess some immunity. As Dr. Alexander Joe points out, the choice of toxin is of the utmost importance, and we are still far from possessing a standardised test material. Nevertheless, the toxin he used gave 95 per cent. of positive results in clinically recognised cases of scarlet fever during the first five days of illness, and 88 per cent. of negative results in persons with a previous history of scarlet fever. Dr. F. A. E. Silcock tells us that five of his cases at first clinically diagnosed as scarlet fever were found to give a persistently positive reaction, and none of them desquamated or showed any complication suggestive of scarlet fever. Further than this a strong positive reaction in contacts suggests that the disease is incubating. Negative reaction means either that the individual is immune, or that there are sufficient quantities of antitoxin circulating in the blood, as a result of previous infection or subinfection, to prevent development of the fever. Only about 20 per cent. of persons fail to acquire this immunity before 20 years of age. The test is undoubtedly effective in separating the susceptible from the immune. Recent work from the Birmingham City Fever Hospital continues[2] the work of the Dicks on the toxin of *Streptococcus scarlatinæ*. Although this organism does not completely fulfil Koch's postulates, it is pretty generally accepted as the causal parasite of scarlatina, and Dr. H. Henry and Dr. F. C. Lewis have concentrated on the preparation and standardisation of the toxin of this micrococcus. Their work indicates that the value and reliability of the Dick test is relative, and relative also is the immunity to the *S. scarlatinæ*, whether natural or acquired. A sufficiently small dose of the toxin will produce a negative reaction in all subjects, and a sufficiently large one will make them all positive. While they aim at the standardisation of the dose in some form of unit, they opine that the toxin-antitoxin combination on which the immunity depends is itself unstable and liable to dissociation.

The use of the Dick method for immunisation is on a less proven footing. The general conclusion seems to be that it is possible to produce immunity in 90 per cent. of susceptible persons by introducing large doses of scarlatinal toxin. Dr. George Buchan, in his recent presidential address to the Society of Medical Officers of Health, stated his opinion[3] that the Dick test and immunisation, or some modification thereof, should be made available in this country for those who would secure protection for their children against scarlet fever. He regards the task as a matter for local sanitary authorities, and points out that it would well repay these bodies to employ an epidemiologist to devote himself to the prevention and control of infectious diseases. Acting on this view the health department of the City of Aberdeen has issued a memorandum by Dr. J. P. Kinloch (dated Nov. 23rd) describing Dick testing and immunisation with a schedule of biological products for diphtheria and scarlatina which can be obtained on request at the City Hospital Laboratory. From China comes a report[4] of a new serum prepared from throat swabs of severe cases by a method radically different from that of the Dicks. Dr. S. P. Chen, superintendent of the Government Isolation Hospital at Peking, found the varieties of antiscarlatinal serum previously used of little value in the toxic type of scarlet fever, of which there is a large proportion in North China. Instead of using a toxin as antigen, Dr. E. T. H. Tsen and Dr. P. Z. King, of the Central Epidemic Prevention Bureau, used washed whole bacterial bodies, first dead and then living, after passage through a horse. The animal was immunised with 12 doses of dead cultures, and subsequently with 14 doses of living bacteria, in gradually increasing amounts. In the absence of a conclusive protection test for the scarlet fever streptococcus these investigators found it satisfactory to use in mice a virulent strain of hæmolytic streptococcus from a case of erysipelas. It may here be recalled that O'Brien and Okell found the hæmolytic streptococcus isolated from a case of lymphangitis to give all the Dick reactions. Nineteen different strains of scarlatinal coccus were used by the Chinese workers as there seemed to be trifling differences in growth among them. The serum has only been in use for a year, but as some of the cases regarded at first as hopeless made a good recovery, Dr. Chen issued a preliminary report. Improvement sets in within 48–72 hours after an intramuscular dose of 25–50 c.cm. of the unconcentrated serum, and in spite of continuance of the pyrexia, the patients evidently had turned the corner. Given early, the serum seemed to ward off serious complications and to cut short erysipelas.

DENTAL RESEARCH.

In no department of medicine is inquiry into the nature of disease likely to be better rewarded than in dentistry. Pragmatism is increasingly the spirit of research. Four years ago the Medical Research Council set apart a committee to investigate dental disease on a broad basis, and the second report[1] of this committee has just appeared, containing the results of an inquiry by Mr. N. J. Ainsworth, L.D.S., into the teeth of 4000 children in public elementary schools. The investigation has been of a very arduous and complete character, the statistical reduction of the data being carried out by Dr. Matthew Young, a member of the Research Council's department of statistics. Definite replies are given to the main questions investigated. The calculated dates of eruption of the various teeth were found to correspond fairly closely with those given in dental text-books and generally accepted. The incidence of caries in the permanent teeth was found to be roughly the same in boys and girls, the tooth most often affected being the lower second molar (28·2 per cent. at 12–13 years), the upper lateral incisor being the most immune (0·4 per cent. at 9–10 years). Of the permanent molars the occlusal surface is by far the most frequently attacked; in the pre-molars the occlusal and distal surfaces equally, while it is the mesial surface of the upper incisors which suffers. Caries was found spontaneously arrested in a negligible proportion of the 6753 carious teeth examined—only about ½ per cent., in fact. Hypoplasia was associated with a double susceptibility to caries, and it is the hypoplastic area of the tooth that is attacked. Gingivitis, including slighter forms, was found in one-third of the children examined, older children having a larger proportion of the severer forms. In 23·2 per cent. of all children examined some degree of malocclusion was found.

---

[1] Medical Research Council: Reports of the Committee for the Investigation of Dental Diseases. II. The Incidence of Dental Disease in Children. Special Report Series No. 97. H.M. Stationery Office. 1925. 1*s.* 6*d.*

The recent report [2] of the Research Committee of the Dental Board of the United Kingdom contains the interim reports of the various workers engaged in research under the auspices of the Board. Though the majority of the work is incomplete, it is obvious that dental science will be much enriched by these investigations which have only been made possible by the financial help of the Board. A very important piece of research is being carried out by Dr. W. W, Rosenhaim and Dr. E. E. Walker for the Department of Scientific and Industrial Research, to whom the Board entrusted a series of investigations on dental alloys and amalgams and on substitutes for vulcanite. The work on the silver-tin amalgams is now completed, and the report will shortly be published. It is stated that new facts have been obtained which may throw valuable light on the ageing of silver-tin alloys. Amalgam fillings play so large a part in conservative dentistry that this research is of special importance, and the dental profession is awaiting the results of the investigation with interest. Of equal importance is the research into vulcanisable rubber and its possible substitutes. Dr. Walker states that he has been engaged on the development of a synthetic product capable of acting as a complete substitute for vulcanite in dentures, and that considerable progress has been obtained. The investigation into the histology of enamel caries by Mr. H. C. Malleson has been recently published and has attracted much attention. Mr. Malleson has been successful in devising a technique whereby sections of enamel can be cut after decalcification. This has enabled him to demonstrate the features of caries in enamel with great clearness and to add much to our knowledge of the microscopical phenomena of caries. The work initiated by Dr. J. K. P. Clarke on the bacteriology of dental caries has been continued by Dr. Maclean, who is now engaged in a series of comparative experiments on the *Streptococcus mutans* of Clarke and the *Bacillus acidophilus odontolyticus* of McIntosh and his fellow workers. Dr. Maclean is also investigating the types of streptococci in pyorrhœa. Mrs. M. Mellanby is continuing her investigations into the dietetic and hygienic factors concerned in the calcification of the teeth in puppies, and is now attempting to produce caries in the teeth of dogs and other animals under experimental conditions with a view to studying the factors affecting the immunity of erupted teeth. Prof. J. C. Brash, whose work on the growth of the jaws has already proved so valuable, is continuing his madder-feeding experiments in pigs in regard to the growth of the jaws and the eruption of the teeth. An independent investigation by Mr. Wilson Charles on the growth of bone, also by madder-feeding, makes piquant reading, for Mr. Charles suggests that experiments with madder are of doubtful utility in demonstrating bone growth. Statistical and anthropometric investigations are being carried out by Mr. Ainsworth, Miss V. H. George, and Miss K. C. Smythe. Of these Mr. Ainsworth's report has now appeared and is summarised above. Dr. E. W. Fish has commenced an investigation into the nutrition of dentine during adult life. In his report he states that so far the analyses of dentine show that there is a definite increase in the calcium content during adolescence and a corresponding withdrawal of salts in later life. This would suggest that the structure of the teeth plays an important part in deciding the occurrence of caries, a view strongly supported by the investigations which have been carried out over a long period by Mrs. Mellanby.

Mr. J. T. Carter is investigating the structure of enamel in modern and prehistoric mammals and reptilia. He finds that the enamel pattern is very distinct in the lower primates and insectivora. Mr. Carter has been engaged for a considerable time in studying the comparative structure of enamel. At the time when the tooth of *Hesperopithecus* sustained its disastrous fall, Prof. Elliot Smith suggested that here was an opportunity of putting to the test the views of Mr. Carter, and seeing whether the enamel structure shed any light on the affinities of the owner of the tooth. Mr. Carter's researches have not become widely known, so that the announcement that a memoir on the enamel of fossil mammalian teeth will shortly be published will be welcome news to all interested in dental anatomy. An application for a grant was received from Messrs. R. A. Broderick, H. Round, and Hervey Wyatt to study the association of gastric ulcer and oral sepsis. They proposed to attempt to reproduce gastric lesions in rabbits by inoculation of cultures from patients with gastric ulcer associated with oral sepsis. In other words, this research was intended to repeat Rosenow's theory of elective localisation of bacteria and to test its validity. It is somewhat surprising that the Board, after consultation with the Dental Committee of the Medical Research Council, refused the grant on the grounds that the work did not appear "primarily to be concerned with dental research." Rosenow's views have attracted wide attention both in America and here, and it seems highly desirable that his experiments should be repeated in this country. It is true that their significance is not limited to dental sepsis, but it is chiefly in connexion with infection from the teeth that Rosenow's theory is discussed. It has so important a bearing on focal infection that we cannot understand the attitude which would deny to such an investigation as that proposed by Broderick and his fellow workers the right to be considered as a piece of dental research.

It is sure that all the various researches will not be equally fruitful, but it is certain that dental science will gain much from these investigations which cover so wide a field. Without the financial encouragement of the Dental Board many of these investigations could not have been commenced. Though many dentists have grumbled at the imposition of an annual fee by the Board, yet the fact that the revenue so obtained has enabled the Board to subsidise research on a scale never before approached in the dental profession in this country should reconcile them to this small recurrent obligation.

ARTIFICIAL LIGHT AND X RAY THERAPY IN SCOTTISH HOSPITALS.—The Scottish Board of Health has issued an interim report on Artificial Light and X Ray Therapy so far as they are used in Scottish hospitals and sanatoria, signed by Dr. Lewis D. Cruickshank, and Dr. Ernest Watt. At the moment, the report says, there is no necessity to press for the installation of more equipment for artificial light in sanatoria, but the authorities should not be discouraged from providing it if they wish to do so. It is, however, recommended that a few of the larger tuberculosis clinics in industrial districts should be encouraged to provide suitable light equipment for the treatment of outdoor cases, and that some of the larger child welfare clinics should be equipped with mercury-vapour lamps. In the case of new X ray equipment a certificate of safety should be obtained from the National Physical Laboratory.

Annotations.

"Ne quid nimis."

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

WORK upon the foundations of the new School, which is to be erected in Bloomsbury to the design of Mr. Morley Horder, F.R.I.B.A., and Mr. Verner Rees, A.R.I.B.A., will shortly be commenced, the contract for this work having just been placed. While this work is in progress the working drawings of the building will be completed and the scheme for the engineering services, which have been entrusted to Mr. T. J. R. Kiernan, M.Inst.C.E., will be drawn up. Concurrently with these developments the board of management of the School are taking such steps as are immediately possible for supplementing the facilities at present available for D.P.H. students. A course in Parasitology is already being given to students in the laboratories of the Tropical Division of the School, and it is interesting to learn that arrangements have now been made by the authorities of the School with Prof. R. J. S. McDowall to deliver—with the consent of the King's College delegacy—a course of lectures in Physiology as applied to Hygiene. These will also be given in the premises of the Tropical Division (the old School of Tropical Medicine) at Endsleigh-gardens, Euston. In the Tropical Division itself some important changes are taking place. The School is shortly to lose the services of Lieut.-Colonel A. W. Alcock, F.R.S., the Director of the Department of Entomology, who is retiring under the age-limit. He is to be succeeded by Dr. P. A. Buxton, who has been selected for the post from among ten applicants. Dr. Buxton is now on his way home from Samoa where, for the last two years, he has been engaged upon a research expedition sent out by the former managers of the School of Tropical Medicine. The post of assistant in the Department of Entomology has also fallen vacant through the retirement of Lieut.-Col. H. J. Walton, I.M.S. (retd.), but this post will not be filled until Dr. Buxton has taken over his new duties at some date early in the new year. In the Tropical Division, also, the extended course, which commenced in October, and has attracted students from all parts of the world up to the full capacity of the accommodation, has been strengthened; the Director has been able with the assent of the Air Ministry to secure the services of Wing-Commander H. E. Whittingham for a series of lectures on Biochemistry, and a short course by Lieut.-Colonel A. J. Gage, I.M.S. (retd.), on Poisonous Plants is being added to the curriculum. The appointment of Lieut.-Colonel G. E. F. Stammers, R.A.M.C. (retd.), to the post of lecturer in tropical hygiene marks a further notable development in the work of the School. The following subjects will be embraced by this course: Tropical and subtropical climatology, personal hygiene, maternity and child welfare, housing in the tropics, food and dietetics, hygiene of food, water, excreta and refuse, disinfection and disinfestation, health measures, hygiene of native labour in the tropics, disposal of the dead, public health administration, and organisation in the tropics. In addition to the lectures given on these subjects at Endsleigh-gardens the students will be taken by Colonel Stammers to see demonstrations, in and about London, in milk-supply, water-supply, sewage and refuse disposal, disinfection, and meat inspection, and a whole day will be given to a visit to the Army School of Hygiene at Aldershot. This extended programme in the study of tropical hygiene, although forming part of the general course of the Tropical Division, will be a self-contained course for which the School are prepared to accept a limited number of students at a fee of £6 6*s.* The lectures and demonstrations will extend over a period of about three weeks from Jan. 13th to Feb. 4th, 1926. The subject of hygiene as applied to tropical medicine has not received in the past its due share of attention, but this has now become possible owing to the extension of the length of the School course, which we have already brought to the notice of our readers.

RECENT CANCER RESEARCH IN ITALY.

Prof. G. Tizzoni and Prof. E. Centanni, of the Universities of Bologna and Modena, have lately published a joint preliminary note on the Modifications produced by Radium on the Pulp of Adeno-carcinoma in Mice and its Transformation into a Curative Vaccine.[1] They base their researches on the principle that the most efficient weapon with which to attack a disease caused by a virus lies in the pathological products evolved by the development of the virus itself. It is not necessary that the nature of the virus, to which Gye and Barnard have drawn attention, should be known. In many diseases due to a filterable virus, such as rabies, small-pox, infantile paralysis, encephalitis lethargica, glanders, &c., practical scientific results have been achieved, although in ignorance of the morphological characters of the virus. In these cases the essential solution of the problem consists in finding, for such products as contain the virus in a natural culture, the conditions under which the death of the virus can be effected without injuring its vaccinating properties. With this idea the present researches were undertaken, using the mammary adeno-carcinoma of mice as the subject and pure radium bromide, one-tenth of a gramme, as the destructive agent. It was found that cancer pulp subjected to radiation for not less than 24 hours when injected into the tissue surrounding the tumour in quantities of $\frac{1}{2}$ c.cm. arrested its growth and caused a gradual regression ending in complete disappearance. Cancer pulp subjected to radiation for a less time was found not to have this property, and when radiated for 40 hours was likewise inactive, having lost both its pathogenic and vaccinating power. These results seem important and are comparable to the attenuation of the virus and its transformation into a vaccine which was one of Pasteur's greatest discoveries. Control experiments were made with the pulp which had been frozen for 24–40 hours without being exposed to the action of radium and also with saline solution in doses of $\frac{1}{2}$ c.cm. which had been irradiated. Both these proved to have no effect on the neoplasm. The control experiments led to the conclusion that the effect of the radiated pulp is not due to induced and acquired radio-activity, nor to its preservation on ice, but to its transformation into a curative vaccine. What these observers appear to have achieved is to have been able to destroy entirely by means of radium the pathogenic power of cancer pulp while retaining either completely or in large proportion its vaccinating properties. Prof. Tizzoni and Prof. Centanni are continuing their work on this vaccine to ascertain more particularly if and under what conditions it retains its activity, and if equally in a dry or liquid state; if a greater concentration and conservability is possible; if it can be purified from inactive and extraneous matter; if it acts only locally and in the zone surrounding the tumour, or whether it has the same efficacy when injected at a distance so that its use would not be limited to external tumours or those in easily accessible situations. Another important matter is to solve the question whether every vaccine is specific exclusively for the tumour from which it is derived, or whether the vaccine from one tumour has the polyvalency necessary to make it of use in other varieties of tumour. In the light of the discoveries of Gye and Barnard this particular vaccine may be able to attack either the generic factor, in which case its task would be rendered easy, or, on the contrary, the specific factor, in which case great and sometimes insurmountable practical difficulties would be met with, and it would be necessary to establish precisely the amount of radiation to be used in each special case. So far we have been summarising without comment the work of the Italian investigators. The method of inducing resistance to tumour growth by the introduction of irradiated tumour material is, however, not new. It was first used by Contamin in 1910 and subsequently by Russ and his collaborators in 1914 and 1922, with results which seemed to show that such a procedure induced resistance against subsequent inoculation, and even against the growth of unestablished tumour. But quite recently experiments on a large scale[2] have shown all these claims to be unfounded.

THE PHYSIOLOGY OF TASTE.[3]

THIS book is, we believe, the first complete translation into English of Brillat-Savarin's famous "Physiologie du Gout," and appears exactly 100 years after the completion of the famous original. The publisher has made of its production in appropriate and shapely form a labour of love, and has, we understand, supplied the translation himself, an exploit upon which he is to be thoroughly congratulated, for Brillat-Savarin is not an easy author to follow justly and fully in any language but his own. The "Physiology of Taste" is a long book, though not so long as might have been expected from the probability that its preparation occupied many years and much note-taking in totally different milieux. As a rule, when the great epicurean is quoted the extracts are taken from two particular chapters, one treating of gourmandism as a whole and dealing with the pleasures of the table, and the other dealing discursively with gastronomy. Such excerpts give only the slightest indication of the range of Brillat-Savarin's knowledge, eloquence, wit, and multiplicity of personal experience, as evidenced by his familiarity with classical authors and English novelists, the princes of French literature, and a host of other French writers. All these are laid under contribution, while the medley is kept interesting throughout by appropriate anecdotes, amusing renderings of personal sensations, sound physiology, and records of life and travel in various parts of the world. The reader will gain from this book, therefore, a very different impression of the author than he is likely to have derived from the frequent allusion to him and his work in general literature, where he usually appears as a great cook, a sort of rival to Ude or Francetelli, especially to the former, who himself wrote a treatise entitled "La Science de Gueule." Brillat-Savarin was not a cook any more than he was a doctor; he was a barrister who held high legal offices, a municipal authority, a politician and perhaps a trifle of conspirator, an antiquary, a country gentleman and sportsman, a frequent host, and an honoured guest at distinguished tables. All these sides of him appear in the "Physiology of Taste," and though in the sense in which the word is used by science he cannot be called a physiologist, there are passages and, indeed, whole pages in his work which will be appreciated by medical men.

Brillat-Savarin awards a high place among "gourmand professions" to that of medicine. Its members, he says, "are gourmands by seduction, and would need to be made of bronze in order to resist the force of circumstances. The dear doctors are the more welcome wherever they go, because health . . . is the most precious thing in the world. Always anxiously awaited, they are sure of the most flattering reception. A pretty patient summons them; youth greets them with caresses; a father, a husband, surrenders his dearest to their care. Hope turns their right flank, gratitude their left; they are fed at the beak like pigeons, and must needs submit; in six months the habit is upon them, and they are gourmands past redemption."

Mr. Davies's fine translation is embellished with some excellent designs by Mr. Andrew Johnson.

HEALTH ON BOARD SHIP.

THE latest report of Dr. J. Howard Jones, medical officer to the Newport Port Sanitary Authority, contains an indictment of the Board of Trade as the Government department responsible for looking after the health conditions of seamen. Dr. Jones points out that the 1923 Instructions to Surveyors as to the Survey of Masters' and Crews' Spaces do not differ materially from those issued in 1913, and that many of the British regulations, in contrast with some of those issued by other countries, are merely suggestions which can be and are ignored by builders. Section 15 states that officers' and engineers' quarters should be so placed that they are entered from a passage-way rather than from the open deck. In spite of this, several new vessels have been at Newport with cabin entrances so exposed that the cabins cannot be kept dry under bad weather conditions. Section 15 also advises that the men should be berthed above decks in houses or poops rather than in forecastles. "Yet," writes Dr. Jones, "on a ship recently built for local owners the seamen and firemen were housed in a narrow confined forecastle in which two of the berths or cots were placed in the narrow triangular space at the forward end of the forecastle, consequently there was hardly room for the men to move about in their quarters, and those berths had to be unshipped to allow of access to the forepeak through the hatchway in the floor for the lowering of ship's gears' stores into the forepeak." The vessel referred to contained many other flagrant defects, rendering her living quarters unsatisfactory, but she had satisfied the Board of Trade owing to the fact that the Board only suggests certain things, which should be strict requirements. As to the lighting of crews' spaces, the new regulations are, says Dr. Jones, less satisfactory than the old, in that the use of electric light instead of daylight is permissible to a greater extent than formerly. In view of the prevalence of tuberculosis among seamen, especially Lascars, a better standard of lighting is very necessary. Section 26 states that in new foreign-going ships suitable bath-rooms and washing places should be provided for the men. This is not compulsory, however, for recently a new foreign-going ship visited Newport without such accommodation. The old practice of whitewashing the walls of crews' spaces is dying out and being replaced by the much better practice of using white paint or enamel. Dr. Jones describes the testing of a certain distemper or water-paint advocated for this purpose, for which antiseptic properties were claimed. It was found that staphylococci and diphtheria bacilli grew quite freely on culture media when mixed with this distemper made up according to the instructions. Dr. Jones gives a description of the crews' spaces of a new vessel to illustrate the lack of common sense frequently shown in designing.

> "The lighting on the men's quarter in the poop was seriously affected by the placing of four berths in both the firemen's and sailors' quarters against the ship's side, in consequence of which the lower bunks and most of the lower parts of the quarters were very dark. The quarters were cramped owing to the fact that the passage-way between the firemen's and sailors' quarters leading to the stores was unnecessarily wide. There was sufficient space available in the poop to provide two excellent berth cabins, a mess-room and bath-room or wash-house. Owing to the lack of bath-room or wash-house, the washing in wet weather would have to be done outside or in the combined living, feeding, and sleeping rooms or in a foul w.c."

Dr. Jones refers to the incomplete mortality tables for seamen published by the Board of Trade and the Registrar-General respectively. The Board returns give no idea of the fatality of certain diseases among seamen because the deaths only refer to so-called bona-fide seamen who die at sea and to those who are discharged from their ships on account of illnesses or injuries which prove fatal. Dr. Jones does not think that more than 10 per cent. of the deaths of seamen from tuberculosis are included in the Board's returns. He sums up the position by saying that the time is long overdue for a thorough revision of standards and of sickness statistics of seamen in the mercantile marine.

SMOKE ABATEMENT.

THE chief obstacle in the way of public health authorities who desire to effect an abatement of the smoke nuisance within their areas is contained in Section 91 of the Public Health Act, 1875 (repeated in Section 24 of the Public Health London Act, 1891), wherein it is laid down that before smoke can be deemed to be a nuisance within the terms of the Act it must be "black" smoke. A factory chimney, whether in London or elsewhere, may belch forth volumes of dense, acrid, brown smoke of a suffocating character and in quantities which cause a pall to hang over the neighbourhood, and yet, under the terms of existing Public Health Acts, no notice can be served by the local authorities. It is possible that some manufacturers deliberately dilute their black smoke with steam in order to keep within the letter of the law. The Public Health (Smoke, &c., Abatement) Bill, introduced by Dr. A. Salter in the House of Commons on Dec. 10th, provides that any chimney emitting smoke in such quantity as to be a nuisance shall be deemed to be a nuisance notwithstanding that the smoke is not black smoke. Dr. Salter's Bill further provides that the term smoke shall include soot, ash, grit, and gritty particles. At present a chimney may emit immense quantities of thick dust or grit which may descend and cover everything in the neighbourhood with a heavy layer of dust, yet the offender cannot be dealt with because his chimney had not given forth black smoke. In order to have some criterion in case of prosecution the Bill provides that every local authority shall make by-laws prohibiting the emission of smoke in excess of a standard fixed by the Minister of Health, and the Minister is directed to fix such standard to which every local authority shall have regard when making the by-laws. It is intended that the Minister shall issue a colour test card to guide the inspector in making his observations and in deciding on a prosecution. Such graded cards are already well known in public health circles. Present penalties for contravention are too trivial to command attention from big manufacturers; increases are suggested from £5, £2, and 10s. to £50, £5, and £1 respectively. In London the suggested authority for the administration of the Act is made the London County Council rather than the borough councils, which are more susceptible to pressure from ratepayers and factory owners. A chimney is defined as including smoke-stacks, structures, or openings of any kind whatsoever capable of emitting smoke, as in the past there have been technical difficulties under this head. Chimneys of private dwelling-houses are specifically excluded, as the promoters of the Bill do not deem it practicable at the present time to issue a general prohibition of open coal fires. Should the low carbonisation treatment of coal at the pithead, the extraction of by-products, and the production of smokeless fuel become an economic possibility, the Act could be extended to deal with domestic chimneys. Section 4 of the new Bill runs: "It shall be the duty of a local authority on submitting proposals for the provision of houses for the purposes of the Housing Acts, 1890 to 1924, to satisfy the Minister that suitable arrangements are to be made for heating or cooking as are calculated to prevent or reduce the emission of smoke." In several recent housing schemes arrangements have been made either for (1) the complete elimination of coal fires and the substitution of gas or electricity for heating, or (2) central heating on the Dundee system. Outside London the County Council is to be given power to supersede any local authority which fails to carry out its duties under the Act of 1875. Any local authority is also to receive power in coöperation with manufacturers or others: (1) to inquire into or devise upon the methods employed in the prevention of smoke and the treatment of smoke in manufacturing operations, and as to the heating arrangements of large buildings; and (2) to arrange for the training of stokers in the best method of stoking. Certain authorities in the North have voluntary schemes on these lines without statutory sanction. Section 3 of the Bill provides for the extension of the list of noxious and offensive gases as enumerated by Section 27 of the Alkali, &c., Works Regulation Act, 1906. The Minister of Health may, after a public inquiry and after consultation with the local authorities or other interests concerned, make orders extending this list and amplifying the list of works mentioned in the first schedule of the Act. These are the main points in a Bill whose beneficent intent is beyond question.

A GRAPHIC SCHOOL REPORT.

IN his annual report for 1924 to the Cheshire County Council Dr. Meredith Young represents school medical service as by no means the dull, routine, wearisome work that it is sometimes painted, but as crowded with human interest. It is easy through his eyes to visualise the mother who "could not make" her child, aged 5 and suffering from "nerves," go to bed before she did; the parents whose children will not sleep in daylight; and the health visitors whose tact is tried to the utmost in efforts to convert "unclean" children into clean. The reported value of X ray for ringworm is generally accepted, but the statement that school lighting seems to affect the number of children with defective vision calls for statistical verification. A special inquiry into thyroid enlargement is of interest; the condition is most prevalent in the west and south of the county; at age 8 it is about equally prevalent in boys (2·3 per cent.) and in girls (2·5 per cent.), but at age 10 the percentages are 3·4 and 13·0 respectively, and at age 13, 4·0 and 16·0. Iodised salt is to be given a trial in the county. The rural child is reported not to compare favourably with the town child. "The rosy-faced, chubby country child is conspicuous by its absence. Instead we find children who are commonly pale, thin, and tired-looking . . . . overcrowding is very general and the older cottages are often vermin-ridden. . . . Villages send their milk, butter, and eggs to the large towns; there is not always left the supply sufficient for the villagers themselves." The children, badly shod, often walk in all weathers long distances on a hasty breakfast carrying with them a lunch of sorts. A dietary lacking in fresh vitamins is customary and anæmia is more prevalent than among town children; efforts to supply mid-day dinners are on foot. It is not a happy picture, but even so the rural child is rather better nourished and suffers less from rickets than the town child in the county. Bad clothing, poor nutrition, and unsatisfactory home conditions are found highly correlated; nevertheless, continued unemployment has not exerted an adverse effect on child physique. Rheumatism was found "equally common in urban and rural districts, in hilly and low-lying country; . . . it may well be considered pandemic." A positive correlation is reported between the stigmata of rickets and those of acute rheumatism. "I would almost hesitate," writes Dr. Young, "to diagnose a rheumatic condition in their absence." The combination of brilliant mentality and debilitating rheumatism is not uncommon, and a vicious circle is established when the child prefers to sit at home reading. Over-scholarship, combined with lowered vitality, is a real danger to these future brains of the country. Such problems are no doubt present in large measure in other parts of the country, but they are set out very pointedly in the report of the chief school medical officer for Cheshire.

PHYSICAL RESEMBLANCE AS EVIDENCE IN CASES OF DISPUTED PATERNITY.

THE Scottish law courts have once more rejected evidence of physical resemblance between child and alleged parent in a case where paternity is in dispute. In preliminary proceedings in his claim to the Seafield peerage Mr. Alexander Grant, who seeks a judicial declaration that he is the eldest lawful and legitimate son of the seventh Earl of Seafield, proposed to offer evidence that not only he himself but also his daughter and other members of his family resembled his alleged parents in feature, gait, and personal mannerisms. Lord Ashmore made an interlocutory order excluding these averments; from that order Mr. Grant appealed, but the Second Division of the Court of Session has (according to a report in *The Times* of Dec. 19th) dismissed his appeal with costs. It will be recalled that ten years ago in the Slingsby case an attempt was made to establish in the English High Court the legitimacy of a boy of 4 years of age by offering evidence inter alia of physical similarities between the child and his reputed parents. On appeal the House of Lords did not look with much enthusiasm upon evidence of this kind; Lord Shaw in particular, speaking with the authority of a Scottish lawyer, pointed out that in Scotland such evidence had been rejected for more than a century on the ground that it was "loose and fanciful," and added that in England it was open to the same objection. In the Seafield peerage claim Lord Anderson repeated Lord Shaw's two epithets, while the Lord Justice Clerk commented on the remoteness of investigating alleged resemblances unto the third and fourth generation. It was proposed, he said, to find resemblances to her grandfather in a grand-daughter. When he surveyed the vista opened up by these averments, he thought in Prof. Bell's phrase, that the situation would make wild work of the law of legitimacy. English law is not quite so rigid as Scots law in excluding evidence of this kind. It will be remembered that photographs were produced in the Russell divorce case to suggest the resemblance of baby to father, and that in the Slingsby case Sir George Frampton, the sculptor, acted as a kind of informal assessor in assisting the judge to detect details of physical similarity. English law seems to allow that, in cases of disputed paternity, the phenomenon of facial resemblance between parent and child is one which a jury may take into account and may weigh along with other evidence. But even English law must draw the line somewhere, and if in an English court it was sought to trace this resemblance through three or four generations, the judge, if he did not exclude the evidence altogether, would doubtless warn the jury not to pay too much attention to it.

PARATHYROID EXTRACT.

IN discussing the treatment of spasmophilia in young children in THE LANCET of Dec. 12th last, Dr. J. C. Spence commented on the recent work of J. B. Collip and his collaborators in the preparation of an extract from parathyroid glands and in the experimental demonstration of its active properties. In the early part of this year Collip published [1] the method of preparation. This consists in collecting fresh parathyroids from oxen and, after dissection, freezing them at -4° C. The active substance is prepared by extracting the glands with 5 per cent. HCl in a boiling water bath. On cooling, the fat is skimmed off and the fluid is rendered alkaline by the addition of caustic soda solution. Hydrochloric acid is added very carefully until the maximum precipitation of proteins at the iso electric point occurs. This precipitate is separated off, redissolved in alkali, and the procedure is repeated. All the solutions are combined, and herein lies the active principle. The administration of this substance, either by mouth, subcutaneously or intravenously, causes a marked increase in the blood calcium. The actual quantity injected does not seem to matter, but frequency is of the utmost importance. Injection into a parathyroidectomised animal in tetany resulted in rapid cure. Very remarkable general results are described; the viscosity of the blood is greatly increased, the osmotic pressure + 10 per cent., phophates + 100 per cent., non-protein nitrogen up to 400 per cent., blood halogens are decreased 10 to 15 per cent. Cases of infantile tetany and of œdema due to acute nephritis were greatly assisted by the extract. Collip stated[2] that it was possible to kill an animal through hypercalcæmia, the blood calcium rising to 29 mg. per 100 c.cm. In his earlier papers Collip maintained that the substance was of a simple nature, but in later contributions he expresses the opinion that it is probably a complex substance. In later papers the rises in blood calcium content induced by the injection of the extracts are not so great as those described in the earlier papers. The provision of a standardised reliable extract of parathyroid for therapeutic purposes is probably now a matter of time only, though, as we pointed out recently (THE LANCET, 1925, i., 89), it will take many animals to meet even a small clinical demand.

PART II. of the Registrar-General's Statistical Review, giving civil tables of statistics for the year 1924, price 5*s.*, is now on sale at H.M. Stationery Office. It follows close on Part I., recently noticed in our columns, and gives tables of population, of births, of infant mortality, of marriages and places of their solemnisation, for different parts of England and Wales. Public health officials will find it indispensable to consult the tables in Part II. as well as in Part I. for serious study of the vital statistics of their own and other areas. This volume also gives the number of Parliamentary and local government electors in each area of England and Wales. Part III. has still to appear.

AT a recent meeting of the managers of the Royal Infirmary, Edinburgh, reference was made to the retirement from the active staff of Sir Norman Walker, and a minute of thanks and appreciation was read, setting out his association with the infirmary as house physician in 1885, assistant physician for diseases of the skin from 1892–1906, and full physician in the skin department from 1906–1924. The minute goes on: "As treasurer of the Royal College of Physicians, as a member of the General Medical Council, as a medical educationist, and in many other positions of professional responsibility, Dr. Walker exhibited also great administrative and business qualities, and has played a leading part among his contemporaries." In conclusion the managers invited Sir Norman Walker to remain as consulting dermatologist to the Royal Infirmary.

MIDDLESEX HOSPITAL.—The rebuilding fund has now reached £259,000, a fraction over half the estimated cost of £500,000. The women of the Empire are being asked to contribute £50,000 for the Queen Alexandra Memorial Wing. The old Alexandra Ward, which sheltered French refugees during the Revolution, is about to be closed. A complete wireless installation for the 90 beds of the hospital's cancer charity was last week presented by the Wireless for Hospitals Fund.

HOSPITAL POLICY OF THE LABOUR PARTY.—At a conference of the provincial centre of the National Union of Trade Union Approved Societies at Manchester last week a report was presented from the Research Department of the Labour movement on the work of voluntary hospitals, The report declared that the present methods of workers. contributions, patients' payments, and letters of recommendation from lay subscribers are "unfair and objectionable," and that the hospitals ought to be "financed from the rates with substantial grants-in-aid from the National Exchequer." Consideration of the report was postponed.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CLIII.—MASTURBATION IN YOUNG WOMEN.

The term masturbation is here used to cover all means employed in order to experience, through the individual's own body, pleasure which is normally gained in sex intercourse. These means include manipulation of the genitals manually or with instruments, crossing and rubbing the thighs, and indulgence in erotic phantasies without handling the genitals.

When a patient presents herself for treatment, our first concern is to help her to understand the true significance of the habit, for it is merely an outward sign that mental and spiritual development have not advanced hand in hand with physical development. It is permissible for the small child to love his own body and all the pleasures associated with its functioning, but if the growing girl and young woman are to add each her contribution to the evolution of the race, then they must forsake the paths of childhood, where self-love is the dominant note, and advance to a new viewpoint from which they have vision of personal insignificance in comparison with racial development. That this is a true interpretation is proved by the patient's attitude of childish evasion of all the problems of life, and the extreme disharmony into which she is thrown by the ever-recurring remorseful conflict provoked by indulgence in what she regards as a sinful habit. Our duty it is to help her to achieve harmony by facing responsibilities, great and small, and by directing all her faculties in unison to the art of living. A thorough physical examination is absolutely essential in this as in all psychological states, since high endeavour may be brought to naught by the backward pull of physical debility. Any weight or tension in the pelvis must be relieved by attention to constipation, to tight clothing (including the present-day weight-reducing rubber corsets), and to dysmenorrhœa. The latter point is of extreme importance, as the period of congestion preceding the onset of the menses is a critical time, during which an orgasm may occur in sleep, even if temptation has been resisted by day.

Before entering on further details of treatment, it is helpful to trace the habit back to its roots, which may be in early childhood or in girlhood. This at once destroys the plea put forward by the patient that she is helpless in the grip of an inborn or, as she may say, hereditary weakness, against which resistance is futile, and thus she can be led to accept personal responsibility. And investigation of the origin of the habit may in other ways prove helpful. In one case, for instance, a patient, badly in the grip of masturbation, expressed great disgust at the obsessive power in her thoughts of enema-syringes in association with certain shops in Charing Cross-road, where these and other appliances are displayed. On carrying back her thoughts to childhood, her earliest recollections of self-abuse were found to be inseparable from the administration of enemata for an extreme degree of constipation. An enema syringe was thus found to be (in the subconscious) not a thing she hated but the motif of her sex-phantasies and the instigator of indulgence. The Charing Cross-road shops were also proved to give, in reality, an additional fillip to her phantasies, and to heighten the pleasure of masturbation.

Early to bed and early to rise is an excellent adage to recommend, while the tonic effect of a morning cold plunge (for those who react with an exhilarating glow) is undoubted. A sedentary life sets an obstacle in the path of progress, not only because it produces, or retards recovery from, constipation, but also because periodically it gives rise to a pent-up feeling which demands an outlet and finds it most easily through indulgence in masturbation. Although the opposite point of view has been put forward—i.e., that an exhilarating walk has a provocative effect on one who is predisposed to masturbate, it is the general experience that subsequent fatigue negatives the initial sense of desire (should it occur), so that we can confidently recommend physical exercise in excess.

Strict avoidance of enervating atmospheres (moral as well as material), of openly or subtly erotic literature, plays and conversation, must be earnestly urged, so long as the patient is still traversing marshy ground, since these may turn victory to defeat. Many women have found, to their dismay, that intellectual work which has not proceeded smoothly is apt to provoke sex feelings. If this be the experience of the patient under treatment, then every effort must be made to reorganise her life till she is on terra firma. But it is absolutely essential that the alternative work suggested should demand a keen coördination of all her energies in achievement and thus provide an adequate outlet for her sex urge.

It may be well to repeat here, what has been said often before, that the modern psychological attitude towards masturbation as retarded development and not a sin must be made very clear to the patient, since the object of treatment is to concentrate on development and to discourage the negative attitude of resistance to temptation and remorse over failure. It is frequently necessary to repeat the explanation with varied phraseology and, as the patient's confidence is gained, to drive it home with illustrations gleaned from her own account of struggle and failure. However much we endeavour to capture the patient's imagination with the lure of an adventure in development, she must at the same time feel the support of practical ideas. To one patient, incredibly childish in her outlook on life, the suggestion was made to attack the problem of growth by making a list of minor evasions of responsibility. Among them she included: failure to brush the teeth regularly, inability to rise when wakened, dawdling over dressing, and unpunctuality.

Many authorities have advocated manual, outdoor labour as the most satisfactory solution for refractory cases, but it is possible, when such an arrangement is not feasible, to provide the right atmosphere in quite other surroundings, as proved by a report received recently from a woman of 41 who had masturbated since childhood, and for some years earned her living with the minimum of effort in wealthy families. Writing from the institution in which, at the suggestion of the writer, she had accepted work, she said the life there had been incredibly hard and even painful, but that never once, since her arrival six weeks previously, had she even experienced any temptation to masturbate.

From these few suggestions on treatment, it is obvious that atmosphere is the most important element in successful handling, and that even at the first interview the patient should, so to speak, experience the tonic effect of a bracing wind. Everything depends on the physician's capabilities as regards successful investigation, initiative to meet the needs of individual cases, or even the varying needs of one case, sympathetic understanding which begets confidence, and a certain driving force which carries the patient along and which both inspires and energises her. The response to treatment is sometimes very rapid, but some cases make a grave demand upon the physician's patience, initiative, and staying power.

Certain views which are frequently put forward upon the subject of masturbation demand critical attention. Some, for instance, contend that the harmfulness of masturbation is grossly exaggerated, and that it serves a useful end in providing an outlet for sex feelings till marriage becomes possible. Three objections can be opposed to this contention. (*a*) That the injuriousness of the habit consists in the fact already pointed out, that it is an indication of arrest of growth, whereas the world has need of men and women who have attained to the full stature of development; (*b*) that the social ideal to be aimed at is an increasing inter-dependence of the sexes, whereas masturbation renders a woman sexually independent of men; (*c*) this independence may, later, wreck a woman's chances of married happiness, for some women have, even early in married life, fallen back on masturbation because through it they experienced greater satisfaction. Others suggest that an outlet should be found in an irregular union, but overlook the fact that this is a pitiful evasion and not a solution of the patient's problem, if we accept it to be one of growth. Such a course inevitably increases the sense of conflict and disharmony, and brings with it an added burden of secrecy. Still others put forward what appears to be a plausible suggestion in advising the woman to avail herself of an opportunity of marrying, marriage being thus offered as a cure for masturbation. This is surely a poor conception of marriage. If we hold the function of wifehood and motherhood in high esteem, is it not well that the woman in question should first put from her childish things and plough the furrow of self-education with earnestness of purpose, before she attempts the difficult task of adjustment to marriage and motherhood? Also, in view of the fact that marital intercourse may offer a lesser satisfaction than masturbation, is it not better that the woman should first on her upward climb arrive at the point where she discovers that the habit of masturbation has fallen from her life as a worn-out and useless garment? For in some such words has many a one expressed to me the consciousness of increase in mental and spiritual stature.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

A MEETING of the President and General Council of King Edward's Hospital Fund for London, for the purpose of awarding grants to the hospitals and convalescent homes for the present year, was held at St. James's Palace on Dec. 15th under the presidency of the Prince of Wales.

Death of H.M. Queen Alexandra.

Lord Stuart of Wortley (Chairman of the Management Committee) moved the following resolution:—

> "That the General Council of King Edward's Hospital Fund for London desire to record their deep sorrow at the death of Her Majesty Queen Alexandra, and their sense of the great loss which all connected with hospitals, in common with the rest of the nation, have suffered thereby. The Council desire respectfully to tender to His Majesty the King, Patron of the Fund, and the Royal Family, their heartfelt sympathy in the sad bereavement which has befallen them, and to offer the humble assurance of their loyalty and devotion."

Lord Somerleyton (hon. secretary) seconded the resolution which was carried unanimously, the Council rising in their places.

The Financial Position.

Lord Revelstoke (the hon. treasurer) said that it had been decided that the total of the ordinary distribution should be increased from £235,000 to £245,000, while it was also proposed that the special grants which they were able to distribute as the outcome of the legacies of the late Mr. and Mrs. Wells should amount to £57,000, the two distributions together making a total of £302,000. The increased distribution of £245,000 would be provided out of the income for the current year. Receipts from legacies were again considerably below the average; but, on the other hand, the Fund had received some most timely donations, including £6000 and £2250 from donors who wished to be anonymous, in addition to £5000 from Lady Strathcona. The British Charities Association, which gave £15,000 last year for distribution amongst hospitals in London, had this year given £20,000. A further amount of £85,485 10*s.* in connexion with the estate of Lord Mount Stephen had also been received. Apart from considerable funds retained for certain annuities, to which the Hospital Fund would be entitled to an eventual reversion, the sum he had the pleasure of reporting as already actually received in this connexion was no less than £666,889. A further £4500 had also been received from the estate of Mr. Samuel Lewis. These sums had, like previous receipts from the same sources, been placed to capital account. From the Wells Legacies, which were estimated at £200,000, the amount received to date was £162,240. If this year's grants were added to last year's, the total allocated so far was £138,000.

League of Mercy.

Sir William Collins, in making the annual statement on behalf of the League of Mercy, said the League approved the policy in regard to contributions from patients, so far as they were voluntary thank-offerings; but they associated themselves with Lord Cave's Committee in the hope that the policy would not work to the detriment of the indigent sick or prevent the admission of the very poor for whom the hospitals were primarily intended. So far as it was possible to estimate from the amounts already received, the League would be in a position this year to hand over £15,000 to the King's Fund, which was £500 more than last year. That would make the total of the contributions by the League of Mercy to the King's Fund £383,034. In addition, they were making grants of £9845 to extra-metropolitan hospitals, and in that they had to acknowledge the assistance of the British Charities Association, which gave £5000 towards that distribution. That made a grand total of the amount distributed by the League of Mercy in its 26 years to voluntary hospitals of £457,084.

Grants to Hospitals and Convalescent Homes.

The Chairman of the Distribution Committee (Sir Cooper Perry) presented the report of the Committee on the distribution to hospitals (including recovery and convalescent branches). The report stated that the amount placed at the disposal of the Distribution Committee for allocation amongst hospitals and their recovery and convalescent branches at the present distribution was £243,000, as against £233,000 last year. The number of hospitals applying for grants was 133, as against 118 in 1924. Taken as a whole, the hospitals continued to maintain in 1924 the improved financial position which had been gradually reached since the crisis in 1920, but additions were being made to the number of beds available, and the Distribution Committee found it necessary to make a considerable increase in the amount allocated to maintenance grants, the total being £214,075, as against £197,275 in 1924.

Prof. Winifred Cullis seconded the report, which was adopted.

Major Wernher (hon. secretary) presented the schedule containing the list of awards to hospitals (including recovery and convalescent branches) as follows:—

*List of Awards.**

	£
Acton Hospital (of which £500 to deficit on extension, in accordance with the scheme submitted to the Fund) ..	1,000
All Saints' Hospital	50
Babies' Hospital (Deptford Fund)	25
Baby Clinic Hospital (Kensington)	25
Beckenham Cottage Hospital	400
Belgrave Hospital for Children (of which £1000 towards the provision of new nurses' accommodation, in accordance with the scheme submitted to the Fund) ..	2,350
Blackheath and Charlton Hospital (of which £50 towards kitchen improvements)	250

---

* The Distribution Committee draw attention to the fact that it must not be assumed that the reduction or absence of a grant implies dissatisfaction.

	£
Bolingbroke Hospital (of which £1000 towards erection of new ward block, in accordance with the scheme submitted to the Fund)	2,350
Brentford Cottage Hospital (of which £500 towards rebuilding and extension on new site, in accordance with the scheme submitted to the Fund)	525
British Hospital for Mothers and Babies, Woolwich	500
Bromley Cottage Hospital	100
Carshalton and District Hospital	100
Central London Ophthalmic Hospital	600
Central London Throat and Ear Hospital	150
Charing Cross Hospital	4,000
Chelsea Hospital for Women (including Convalescent Home at St. Leonards)	875
Cheyne Hospital for Children (including Country Branch at St. Nicholas-at-Wade) (of which £250 towards increased accommodation for artificial sunlight treatment and other improvements, in accordance with the scheme submitted to the Fund)	500
City of London Hospital for Diseases of the Heart and Lungs (Victoria Park) (including Convalescent Home at Saunderton)	3,850
City of London Maternity Hospital	1,250
Clapham Maternity Hospital	350
Dreadnought Hospital (Seamen's) (including Albert Dock Hospital, Hospital for Tropical Diseases, Sanatorium at Liphook, and Convalescent Home at Cudham) (of which £100 towards provision for artificial sunlight at the sanatorium at Liphook)	2,650
East End Mothers Lying-in Home (of which £1000 towards acquisition of adjoining building and its adaptation for nurses' quarters, in accordance with the scheme submitted to the Fund)	1,500
East Ham Hospital	150
East London Hospital for Children (including Convalescent Home at Bognor) (of which £100 to complete the extension and improvement of the X ray department)	3,350
Elizabeth Garrett Anderson Hospital (including Recovery Branch at Barnet) (of which £1000 towards extension, in accordance with scheme to be approved by the Fund)	2,725
Eltham and Mottingham Cottage Hospital	25
Enfield War Memorial Hospital	200
Evelina Hospital	1,000
Finchley Memorial Hospital	275
Florence Nightingale Hospital for Gentlewomen	300
Forest Hospital, Buckhurst Hill	175
French Hospital	350
General Lying-in Hospital	650
German Hospital	350
Gordon Hospital for Fistula	50
Grosvenor Hospital for Women (of which £500 towards provision of accommodation for resident medical officer and for nurses, in accordance with scheme to be approved by the Fund)	1,000
Guy's Hospital (of which £2000 towards recent improvements)	12,500
Hampstead General and North-West London Hospital (of which £250 towards improvements, in accordance with the scheme submitted to the Fund)	3,000
Hanwell Cottage Hospital (of which £25 towards provision of X ray department, in accordance with the scheme submitted to the Fund)	75
Hendon Cottage Hospital (of which £250 towards extension of ward block, in accordance with the scheme submitted to the Fund	550
Hornsey Cottage Hospital (of which £100 to deficit on extension, in accordance with the scheme submitted to the Fund)	250
Hospital for Consumption, Brompton (including Sanatorium at Frimley) (of which £250 towards removal of X ray department from basement, in accordance with the scheme of improvements submitted to the Fund)	1,250
Hospital for Diseases of the Throat	100
Hospital for Epilepsy and Paralysis (of which £500 towards extension of in-patient department, in accordance with the scheme submitted to the Fund)	2,250
Hospital for Sick Children	4,000
Hospital for Women (Soho-square)	1,000
Hospital of St. John and St. Elizabeth	750
Ilford Emergency Hospital	300
Infants Hospital (of which £150 to reduce debt)	500
Invalid and Crippled Children's Society Hospital (Canning Town) (of which £250 towards extension of out-patient department, in accordance with the scheme of extension submitted to the Fund)	700
Italian Hospital	300
Jewish Maternity Home	35
Kensington Dispensary and Children's Hospital (of which £500 towards removal and extension, in accordance with scheme to be approved by the Fund)	525
Kensington, Fulham, and Chelsea General Hospital (of which £1000 towards rebuilding and extension, in accordance with the scheme submitted to the Fund)	1,100
King Edward Memorial Hospital (Ealing)	500
King Edward VII.'s Hospital for Officers	250
King's College Hospital	7,500
Kingston-upon-Thames Victoria Hospital	100
London Fever Hospital (of which £25 towards ward kitchen)	525
London Homœopathic Hospital	1,750
London Hospital (including Recovery Branch at Reigate) (of which £1,000 to improvements, in accordance with the scheme submitted to the Fund)	14,625
London Jewish Hospital (of which £500 towards extension, in accordance with the scheme submitted to the Fund)	750
London Lock Hospital (of which £500 to maintenance of Harrow-road hospital and £100 to maintenance of Dean-street hospital, and £1000 towards the building of an extension of the out-patient department at Dean-street, in accordance with scheme to be approved by the Fund)	1,600

Samaritan Free Hospital for Women (including Convalescent Home at Amersham)	1,300
Santa Claus Home	75
Seamen's Hospital Society (*see* Dreadnought Hospital)	
South-Eastern Hospital for Children (Sydenham) (of which £750 towards new nurses' home, in accordance with the scheme submitted to the Fund)	1,550
South London Hospital for Women (of which £500 towards new out-patient department, in accordance with scheme to be submitted to the Fund)	1,500
Stoke Newington Home Hospital for Women	75
Streatham Babies' Hospital	25
University College Hospital (of which £1000 to reduce debt)	8,500
Victoria Cottage Hospital (Barnet)	100
Victoria Hospital for Children (including Convalescent Home at Broadstairs)	2,700
Walthamstow, Wanstead, and Leyton Children's and General Hospital (of which £1000 towards extension, in accordance with the scheme submitted to the Fund)	1,900
Weir Hospital, Streatham	100
West End Hospital for Nervous Diseases	1,600
Western Ophthalmic Hospital	300
West London Hospital	5,500
Westminster Hospital (of which £1000 to reduce debt)	6,150
Willesden General Hospital	1,750
Wimbledon Hospital (of which £200 to deficit on new nurses' home, in accordance with the scheme submitted to the Fund)	550
Winifred House Invalid Children's Convalescent Hospital Home	25
Woodford Jubilee Hospital	75
Woolwich and Plumstead Cottage Hospital	25
Woolwich and District War Memorial Hospital Building Fund (special grant towards provision of general hospital, in accordance with the scheme submitted to the King's Fund)	1,000
Total	£243,000

Summary.

Total Grants to Hospitals (including Recovery and Convalescent branches) out of the ordinary distribution	243,000
Total Grants to Hospitals, January to December, 1925, out of the special distribution of the legacies of the late Mr. and Mrs. Wells	57,000
Total grants to hospitals and branches ..	£300,000

The motion was put and carried unanimously.

Distribution to Convalescent Homes.

The Chairman of the Distribution Committee (Sir Cooper Perry) then presented the report of the committee on the distribution to convalescent homes not attached to particular hospitals, which stated that the President and General Council had fixed the sum available for distribution amongst convalescent homes not attached to any particular hospital in London at £2000, being the same amount as last year. The number of applications eligible for consideration amounted to 42, also the same as last year.

Lists of Awards.

The list of grants were presented by Major-General Sir Cecil Lowther (hon. secretary) as follows :—

	£
All Saints' Convalescent Hospital (Eastbourne) ..	200
All Saints' Convalescent Home (St. Leonards)	25
Baldwin Brown Convalescent Home (Herne Bay) ..	25
Beau Site Convalescent Home (Hastings)	25
Brentwood Convalescent Home for London Children (Brentwood)	25
Brooklands Home (Invalid Children's Aid Association) (Worthing)	50
Bushey and Bushey Heath Children's Convalescent Home (Bushey)	25
Children's Convalescent Home (Beaconsfield)	25
Children's Cottage Hospital (Cold Ash, Newbury) (in consideration of the fact that convalescent cases are admitted	25
Children's Home Hospital (Barnet) (in consideration of the fact that convalescent cases are admitted) ..	25
Clevedon Sanatorium (Invalid Children's Aid Association) (Broadstsirs)	50
Convalescent Home for Children (Hawkenbury, Tunbridge Wells)	25
Convalescent Home for Poor Children (St. Leonards) ..	75
Convalescent Police Seaside Home (Hove)	75
Edgar Lee Home (Invalid Children's Aid Association) (Willesden)	50
Florence Emma Home (Invalid Children's Aid Association) (Dover)	25
Friendly Societies' Convalescent Home (Herne Bay) ..	25
Hamilton House (Invalid Children's Aid Association) (Seaford)	50
Home for Invalid Children (Brighton)	50

Tilford Convalescent Home for Children (Farnham) ..	50
Victoria Home for Invalid Children (Margate) (in consideration of the fact that convalescent cases are admitted)	25
Total	£2,000

The motion, having been seconded by Lord Mildmay, was then put, and carried unanimously.

Wells' Legacies Distribution: Lists of Grants to December, 1925.

The Chairman of the Distribution Committee (Sir Cooper Perry) then presented the report of the committee on the special distribution to hospitals out of the Wells legacies to date, in aid of extensions, and Mr. Leonard L. Cohen (hon. secretary) presented the schedule containing the list of awards to hospitals out of the Wells legacies to date, as follows :—

Beckenham Cottage Hospital.—£3000 towards extension —viz., £1000 towards the deficit on the earlier stages of the scheme, increasing the number of beds from 25 to 40, £1000 to be payable on the completion and opening of the final stage, and £1000 to be the last £1000 required to free the whole scheme of debt; on condition that the final stage is put in hand by the beginning of October, 1925.

Belgrave Hospital for Children.—£2000 towards erection of new wing to be used temporarily for nurses' accommodation so as to enable the hospital to open 12 beds, thus increasing the number available from 62 to 74; to be the last £2000 required in order to secure a conditional donation of £10,000.

Bolingbroke Hospital.—£2500 towards extension from 60 beds to 92, to be the last £2500 to enable the extension to be opened free of debt, on the understanding that the balance is raised by the hospital and that, when the extension is opened, 10 beds will be reserved for accident cases.

Brentford Cottage Hospital.—£1000 towards the building of the new hospital, increasing the number of beds from 7 to 16; on condition that the contract is signed by Jan. 1st, 1926.

Invalid and Crippled Children's Society's Hospital.—£500 towards extension, increasing the number of beds from 28 to 40, as a grant to start the appeal for the scheme.

Jewish Maternity Hospital.—£1000 towards extension from 13 beds to 39, to be the last £1000 required to render the extension free of debt.

Kensington Dispensary and Children's Hospital.—£500 to first stage of rebuilding as Princess Louise Kensington Hospital for Children, on condition that beds are provided as well as an out-patient department.

King Edward Memorial Hospital, Ealing.—£2000 toward extension from 62 beds to 102; being £1000 to start the appeal for the scheme, and £1000 to be the last £1000 required to render the extension free of debt, without depleting the hospital's free capital, on the understanding that the work is put in hand by March 31st, 1926.

London Jewish Hospital.—£2500 towards extension, increasing the number of beds from 51 to 84, and including separate nurses' home and extension of out-patient department; £1250 of the grant to be payable when the nurses' home and out-patient department are begun, and £1250 when the whole scheme is finished.

London Lock Hospital.—£1000 towards the building of the extension of the out-patient department at the Dean-street Hospital.

Metropolitan Hospital.—£5000 towards new nurses' home and accident ward of 9 beds; to be payable as soon as a further £5000 has been raised by the hospital from other sources; on the understanding that the nurses' home will be put in hand by Jan. 1st, 1926, and that, when the ward is opened, 9 beds will be reserved for accident cases.

Middlesex Hospital.—£10,000 in July, 1925, as a first grant to the reconstruction scheme; and £10,000 in December, 1925, as a second grant.

Royal Free Hospital.—£1000 towards new children's ward providing 18 additional cots, on the understanding that, as a result of the consequent rearrangement of hospital beds, 9 beds will be provided for accident cases.

Royal Hospital, Richmond.—£1000 towards extension, increasing the number of beds from 66 to 82; to be the last £1000 required to enable the extension to be opened free of debt; on the understanding that the balance is raised by the hospital without drawing on investments now held for other purposes, and that, when the extension is opened, 4 beds will be reserved for accident cases.

Royal National Orthopædic Hospital.—£5000 towards extension of out-patient department at Great Portland-street; to be the last £5000 required to enable the extension to be opened free of debt, on condition that the work is put in hand by Jan. 1st, 1926; and £3000 towards extension of country branch at Stanmore from 100 beds to 252, to be the last £3000 required to complete the first £40,000 for the scheme; subject to the conditions of the grant of £5000 to the out-patient department extension being fulfilled first.

Royal Waterloo Hospital for Women and Children.—£3000 towards final stage of extension scheme, including new nurses' accommodation, to be the last £3000 required to enable the extension to be opened free of debt.

Willesden General Hospital.—£3000 towards extension, increasing the number of beds from 78 to 100; to be the last £3000 required to open the whole building free of debt; on the understanding that the balance is raised by the hospital without drawing on general fund cash or investments, and on condition that the new ward block is put in hand by the middle of October, 1925, and that, when the ward block is opened, 8 beds will be reserved for accident cases.

The total grants to December, 1925, were therefore £57,000, and the number of additional beds to be provided 396. The number of beds to be reserved for accident cases totalled 40.

Sir Walter Lawrence, Bart., having seconded, the motion was put and carried.

The Prince of Wales here read a message sent by His Majesty the King, the Patron of the Fund, which was as follows:—

> "The King is glad to hear that the Fund has been able to increase its distribution from £235,000 to £245,000, and that with the extended area of its operations it now makes grants to no fewer than 133 hospitals. His Majesty is grateful to Lord Stuart of Wortley for all he has done as chairman of the Management Committee, and, indeed, ever since the foundation of the Fund, of which he was one of the original honorary secretaries."

Remarks by the Prince of Wales.

Continuing, the Prince of Wales said that the distribution this year covered a wider field than ever before, for the King's Fund area was now 380 square miles instead of 255, while the number of hospitals helped had gone up from 118 to 133. The amount of the ordinary distribution had increased from £235,000 to £245,000, apart from the grants out of the Wells legacies. The combined total was £302,000. The ordinary distribution of £245,000 came from various sources. About two-thirds of it was secured by income from investments under the care of Lord Revelstoke and the Finance Committee. But about £82,000 had to be raised in the year. The annual subscriptions had always been smaller than hoped for, but this year they showed a welcome increase, largely in the form of seven-year agreements, many of them so worded that the subscriber gave the King's Fund the benefit of any income-tax saved by the agreement. The League of Mercy provided, as usual, a large sum, made up of innumerable small ones, while donations again included some of those unexpected gifts without which distribution could not be maintained. For the second year in succession the British Charities Association had entrusted the Fund with the distribution of a large sum. Last year the proportion allocated by the Association to London was £15,000. This year their receipts were greater, owing mainly to a competition organised with the coöperation of the *Daily Mail*, and the amount granted to the King's Fund for the hospitals of London was £20,000.

If, however, the income had increased, the demands on the funds were also growing. There were 15 more hospitals on the list, including 11 brought in by the enlargement of the area, and the expenditure of the hospitals was being continually increased by the discoveries of medical science, and by the provision of additional beds. That people sometimes forget. His Royal Highness hoped that no one would think, because the hospitals had, by a great effort, improved their position, that this was any reason for ceasing to subscribe. For every new extension that was opened, and every new discovery in hospital treatment meant a fresh call for expenditure. Taking extensions alone, the King's Fund, by devoting the Wells legacies largely to this purpose, had been helping to provide 697 additional beds, which would all have to be maintained. The Management Committee went into the whole question of extensions last year at the request of the Voluntary Hospitals Commission. Their conclusion roughly was that, whatever might be the total number of beds required, the immediate need was to expedite the schemes for the provision of the next 2000 beds, after which it would be time enough to face the more distant future. The Commission, in their recent report, accepted this estimate for London, and added another 8000 for the rest of England and Wales. The Distribution Committee had kept in mind the provision of more accident beds. Another 40 would be added with the aid of this year's grants, making, with 53 last year and 20 provided without assistance from the Fund, a total of 113 since the report of the Fund's Ambulance Cases Committee was published. His Royal Highness, in his conclusion, referred to the memorandum on pensions for hospital officers and nurses (vide THE LANCET, Dec. 19th, page 1299), in the preparation of which the Fund had taken part, and to the revision of the revised uniform system of hospital accounts, which the Hospital Economy Committee had now nearly finished. Referring to the year 1926, His Royal Highness said that he had appointed Lord Donoughmore as a successor to Lord Stuart of Wortley, who had found the detailed work of management more than he could continue to undertake. He had also appointed Mr. J. H. Thomas, M.P., a member of the Council in the place of Mr. Frederick Hall, M.P., and had added the names of Dr. Louisa Garrett Anderson and Mr. F. W. J. Jackson, while Dr. Morley Fletcher would become an additional medical member of the Distribution Committee.

The meeting closed with the usual votes of thanks.

WESTMINSTER HOSPITAL.—Mr. Austin Taylor, formerly M.P. for East Toxteth, has been appointed chairman of Westminster Hospital, in succession to the late Sir Edward Pearson. Mr. Taylor has for many years been a member of the House Committee of the Hospital.

PROVISION FOR CRIPPLED CHILDREN.—A movement is on foot to provide a hospital and other treatment for crippled children in Devon and Cornwall, and a site near Exeter has been given anonymously. It is stated that between 500 and 600 children in the area are awaiting treatment.

PROCEEDINGS OF THE ROYAL COMMISSION ON NATIONAL HEALTH INSURANCE.

(*Continued from p. 1248.*)

Evidence as to the Question of Proof of Unemployment.
(App. CII. and Q. 23290–23395.)

Mr. J. F. G. Price, a principal Assistant Secretary of the Ministry of Labour, gave evidence with regard to a suggestion which had been made that insured contributors under the Health Insurance scheme who are "genuinely unemployed" should be enabled to have their Health Insurance contribution cards impressed with a stamp at an employment exchange with a view to being relieved of penalties which would otherwise arise under the Health Insurance scheme because of failure to stamp.

Mr. Price's evidence was to the effect that, while it would be practicable to endorse with a rubber stamp the Health Insurance cards of unemployed workmen, it would dislocate the work of the exchanges and that his Department would prefer to give certificates of unemployment on application when loss of sickness benefit was directly at stake. There would be difficulties in any event with regard to agricultural workers and domestic servants, as these classes were not covered by the Unemployment Insurance scheme.

The examination of this witness was directed in the main to establishing that the automatic record at the time of unemployment would be easier in the long run, but the witness was not prepared to assent to this.

Sir Walter Kinnear's further Evidence.
(Q. 23396–23829.)

The Controller of National Health Insurance, Sir Walter Kinnear, was examined with regard to suggestions which had been put to the Commission on various questions other than those relating to medical benefit. The substance of his replies is given in the following paragraphs. The suggested exclusion of bank clerks and insurance officials who may cease to be insured on passing the income limit at an early age would involve difficult questions of demarcation, and there was no reason to think that the workers themselves desired to be excluded. A better way would be for their societies to provide out of their surpluses for treatment benefits for a limited period after the income limit had been passed.

Many persons belonging to the wage-earning classes as ordinarily understood, but not under contract of service, might well be brought within the Act.

> We might provide for compulsory insurance in the case of employment under a contract for the performance of manual labour for the purposes of a trade or business, and that the person for whose business the work is performed should be deemed to be the employer.
>
> The demand for voluntary insurance has been intensified by the passing of the Pensions Act.

The proposal to drop the manual labour test and determine insurability simply by rate of remuneration—possibly increasing the limit to £300 per annum—was open to objection on many grounds. Manual workers, earning high wages, are not in as stable an economic position as non-manual workers, and cannot be expected themselves to make the same provision for insurance.

> A high rate of remuneration does not necessarily mean continuous employment, and . . . you might find that the docker, who was earning a high rate of remuneration for two or three days in the week, would be cut out of insurance, although his total income may not be very much larger than £250 a year.

With regard to the present age limits of 16 and 70, any reduction of the commencing age limit would be a retrograde step, and there is no widespread demand for it; the limit at the other end becomes 65 with the operation of the new Pensions Act. Insurance will cease at 65, and if a man is insured until then he will be entitled to medical benefit for the rest of his life.

A period during which a person is genuinely out of work and may be receiving unemployment benefit should not be counted against him for the purpose of his qualification for Health Insurance benefits.

> It is indefensible that where under one State scheme a man is getting unemployment benefit because of genuine unemployment, concurrently with the receipt of that benefit he should be piling up arrears with the possibility of reduced sickness benefit under another State scheme.

Many witnesses, particularly those representing Friendly Societies, had suggested that a limit should be placed on the extent to which the standard rates of benefit should be allowed to be increased by way of additional benefit. The Department did not think it desirable to place a statutory limit; the Minister's present powers for approving schemes of additional benefits were considered adequate to meet the case.

The Department considers that it would not be practicable or desirable to merge the Workmen's Compensation scheme in the Health Insurance scheme. Such a system could not be worked in conjunction with a general scheme of insurance based on flat contributions. In any case, the Department considers that it would not be practicable for Approved Societies organised on their present lines to administer workmen's compensation insurance.

The provisions with regard to late notice of incapacity might be made less stringent—e.g., in cases where a member had gone into hospital.

With regard to the control of Approved Societies, further powers were necessary for dealing with minor irregularities, withdrawal of approval being much too drastic a remedy in such cases. Where on investigation general laxity was found a reduction might be made in the amount which a Society should be allowed to expend on administration. The Department has no evidence which suggests that the administration of benefits through Approved Societies is not acceptable to the insured population generally. Indeed, the administration of cash benefits by societies works, on the whole, quite well, and from the audit reports it is to be gathered that the standard of their administration has now reached a high average. The administration of schemes of treatment benefits is still largely in the experimental stage. The marked increase in the amount of money devoted to treatment benefits is accentuating the necessity for the administration of these benefits being coördinated through one local committee in each area.

As to the democratic control of large centralised societies, some improvement might be effected by ensuring notification to members of the general meeting and by facilitating the holding of district meetings, but the extraordinary apathy of the insured persons themselves must be recognised.

The original intention of Section 21 of the 1911 Act was to enable Approved Societies and branches without any question of receiving an equivalent return, to make subscriptions or donations to hospitals or charitable institutions which serve the interests of public health.

> The section is now used by a number of societies for the purpose of providing benefits in the nature of additional benefits to all members, whether qualified to receive additional benefits or not, by paying quite considerable sums in anticipation of surpluses to organisations specially set up to receive such payments. . . .
>
> We think the legislature really intended by "charitable institutions" to refer to hospitals and dispensaries and other institutions which provide on a voluntary basis benefits for the population as a whole, and not organisations purely set up for National Health Insurance.

The number of deposit contributors is steadily diminishing and the Deposit Contributors Fund has gradually become a clearing house for the societies except as regards the comparatively small number of persons who either in principle object to joining societies, or are unable to obtain admission to a society by reason of ill-health. Special provision might be made on lines, suggested by the witness, for giving a more effective insurance to those who had tried to get into a society and had failed, but the Department did not recommend the establishment of a State Society.

It is not considered possible to extend to insured women who cease employment on marriage the ordinary provisions as to a free year's insurance.

BERLIN.

(From our own Correspondent.)

Responsibility of Medical Men in Germany.

A medical man in a country town was recently consulted by a mother because her 5-year-old child had broken its humerus near the elbow. He applied a starch dressing with a splint and told the woman to come back in a week unless the child had pain, in which case she should bring it at once. Although the child complained, was sleepless and feverish, the mother did not bring it up for a week, when it was ascertained that gangrene had set in, and eventually amputation had to be performed. The doctor was prosecuted. In court a local expert, giving evidence for the prosecution, said that the medical man should have examined the dressing on the first or second day instead of telling the mother to come in a week; he would then have ascertained that owing to the swelling of the arm the dressing had become too tight and had caused strangulation. Surgeons of great renown, such as Prof. Sauerbruch, of Munich, however, gave evidence for the defendant, saying that the gangrene was probably caused either by thrombosis or by a compression of the brachial artery by the fracture rather than by the dressing. Prof. Sauerbruch stated that in the out-patient department of his hospital the patients in similar cases were always directed to come in a week and to present themselves at an earlier date only if pain was felt. In his opinion the fault lay with the mother and not with the medical attendant. Notwithstanding this evidence the defendant was found guilty of bodily injury by neglect and fined 600 marks; moreover, an action for damages was brought against him by the mother. This verdict is the more remarkable in that the mother, living rather far from the medical man's residence, and notwithstanding the advice of her neighbours, had declined to come earlier on grounds of economy. The Director of Public Prosecutions, Ober-Reichsanwalt Dr. Ebermayer, discusses the legal position in the case in the *Deutsche Medicinische Wochenschrift*. He says that the term "malpraxis"—Kunstfehler—which is so often used in medical and lay circles is not contained in any of the German laws. Malpraxis may be described as an offence against the generally recognised rules of medical science either by insufficient knowledge or insufficient care. A medical man may be prosecuted for that misdemeanour by the Public Prosecutor and is, moreover, liable to pay civil damages to the injured patient. This is, however, only the case when, according to general experience, he could have foreseen that damage might result from his treatment. The damages he has to pay include the prejudice done by his action to the working strength and to the career of the patient. He is held responsible not only for his own mistakes, but also for those of his assistants. Hospitals may be held responsible for the action of their appointed staffs. A medical man may insure himself against the financial consequences of his mistakes. He may also be prosecuted when he has operated on a patient against his will, even when the operation has been performed lege artis and has been successful.

Medical Service in Prisons.

The defects of the prison medical service in this country have recently aroused attention. A former Minister had been arrested for alleged fraud committed whilst in office, and although cardiac debility had been certified by his private medical attendant, he was kept in prison until his death. Apart from the political side of the matter, it was stated in the course of a Parliamentary inquiry that some time ago the Minister of Justice had instructed the medical officers to give a certificate of unfitness for imprisonment only if there was no danger that the prisoner might escape, and not merely for reasons of health. They were further warned against attaching too much importance to private medical certificates, but it was left to their absolute discretion to advise the judge concerning a release on bail of the prisoner. The Parliamentary Committee further stated that the whole medical service in prisons was very unsatisfactory. There existed no whole-time medical officers for prisons; in the greater cities the law court medical officers and in the country the district medical officers of health had to attend prisoners besides their other numerous duties. In the case quoted above it was ascertained that the medical officer lived at a great distance from the prison and that when informed of the bad condition of the patient he gave his prescriptions by telephone. Before the Parliamentary Committee he gave evidence that the hospital connected with the prison contained 200 beds for which four nurses were appointed. He had on several occasions asked the authorities to appoint a resident medical assistant, since he was quite unable, owing to his other work as an expert in lawsuits, to give the patients the necessary attention; his demand had always been refused. Further evidence proved that as a consequence of the inadequate nursing staff the nurses, to keep the patients quiet, gave them indiscriminately quantities of narcotics, which in the case quoted above led to a fatal issue. The result of the inquiry was that the instructions of the Minister to the medical officers were withdrawn and that the number of the medical as well as of the nursing staff was increased.

Mortality of Insured Medical Men.

Dr. Freudenberg has published an interesting statistical record on the mortality of medical men insured in the Medical Life Insurance Company connected with the Hartmann-Bund. The period covered is from 1919 to 1923 and is compared with a similar record of the Gotha Life Insurance Company for the years of 1829 to 1885. The number of medical men involved is 3940 with 217 deaths. Infectious diseases, especially enteric fever, showed a great diminution compared with the Gotha record, owing to the general improvement of hygiene and the successful fight against infectious diseases. Diseases of the central nervous system have also diminished owing to the more efficient treatment of syphilis, and so have pneumonia and pleurisy. The percentage of malignant growths has undergone no change. It is interesting that the percentage of diseases of the heart and the circulatory organs in medical men has exceeded that of the general population, whilst formerly, according to the Gotha record, the contrary was the case. This is ascribed by the author to the circumstance that during and after the war the scarceness of spirits has produced a decrease in the mortality from cardiac diseases in the general population; on the other hand, in the medical profession deaths from those diseases are due not to an abuse of spirits, but to over-exertion connected with medical practice, which now involves a more strenuous life than it did. The distressed condition of the medical profession is, moreover, illustrated by the fact that of the 217 deaths recorded 16 were due to suicides committed between the ages of 46 and 61 years. Formerly suicides at that age were very rare; the average medical man was, as a rule, then able to retire from practice or at least to limit its scope and to enjoy the rest earned by his former work. Now the great mass of medical men must work until their death, and if unable to do so are likely to end as paupers or suicides.

Opilaçao or the Chagas Disease.

The head of the Brazilian Health Office and of the Hygienic Institute in Rio de Janeiro, Prof. Chagas, who is making a tour of Europe,[1] recently visited Berlin and read before the Berlin Medical Society a paper on the disease called after him, which is a form of trypanosomiasis common in Brazil. Prof. Chagas's paper was translated by his countryman, Dr. Rocho de Lima, of the Hamburg Institute for Tropical Diseases. He explained that the parasite which gives rise to the disease was detected before its clinical features were recognised. Its habitat is the intestines of a bed-bug which is found in native huts. In the night the bug bites men and animals, and in this way the disease is conveyed. The acute form of the disease occurs more particularly in children. Fever is always present, and a characteristic symptom is a swelling of the face. When the parasites in the blood are very numerous the patients nearly always die. If the disease enters a chronic stage the parasites are found not in the blood, but in the heart and in the central nervous system. Prof. Chagas is of opinion that a connexion exists between trypanosomiasis and goitre, which is endemic in Brazil.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Vital Statistics for the Third Quarter of 1924.

PROVISIONAL figures for the 90 French départements are compared for the third quarters of 1924 and 1925 by the Minister of Labour as follows :

	1924.	1925.
Marriages	36,095	35,014
Divorces	5,061	4,999
Living births	188,114	190,192
Stillbirths	7,437	7,367
Deaths under 1 year	15,493	17,007
Deaths, 1 year and over	124,228	134,275
Total deaths	139,271	151,282
Excess of births over deaths	48,393	38,910

Vaccination in France in 1924.

In a well-documented report, Dr. L. Camus, director of vaccination at the Academy of Medicine, sets out the story of vaccination and revaccination in France during 1924. Reports from the departments show that obligatory vaccination has been accepted without hesitation except in a few places. Among those who presented themselves voluntarily for revaccination a percentage of 65 of positive results was noted, showing that vaccinal immunity is transient and that it is prudent to renew it from time to time. The percentage of success at primary vaccination was practically 100 per cent. Foreigners have been vaccinated in great number on their entrance into France. At Modane the number was 39,643 ; at Hendaye, 19,773 ; but the organisation has not been so complete at the other frontier stations. Forty-seven cases of small-pox were recorded in 1924. There were two small epidemics, one at Limoges and the other at Carcassonne, due to the sorting of rags. Six deaths were recorded : one at Marseilles, of a seaman who died five days after debarkation, four at Limoges, and one at Carcassonne.

Idiopathic Rise of Temperature.

Dr. Remlinger, director of the Pasteur Institute at Tangier, in a communication to the Academy of Medicine, has described persistent febrile attacks of which searching clinical and biological examination failed to determine the cause. He regards them as idiopathic, arising in subjects of thermal instability as a result of upset of heat regulation. He queries whether climatic factors are not concerned in their production, for in several of the cases, the febrile attacks ceased in France to reappear on returning to Tangier, a town with severe marine climate, the action of which, far from being sedative like the purely marine climate, is particularly bracing. It would be interesting to find out if parallel records of unexplained rises of temperature have been made on the shores of the North Sea or of the English Channel, which have a similar bracing marine climate. It may be that the marine fever of old writers has been denied wrongfully by too fervent disciples of thalassotherapy.

Measles in Paris : The Course of an Epidemic.

Dr. René Martial's account of the evolution in time and space of an epidemic of measles in the environs of Paris is not devoid of interest. The epidemic spread from south to north of the city and was held in check on the west by the Seine and on the east by a line of railway. On the south it was limited by a large tract of waste land and on the north by the Marne. The epidemic progressed slowly, taking nine months to reach from south to north, a distance of only five kilometres. The total number of cases was between 700 and 800 with 12 deaths. A maximum of 159 cases notified during April fell to 23 during June, the school holidays contributing to the disappearance of the epidemic.

A celebration is being organised for the seventy-fifth birthday of Charles Richet, professor of physiology at the Faculté de Médecine, which will also mark the completion of his fiftieth year as teacher and laboratory worker. Subscriptions may be sent to Mr. Pettit, treasurer of the committee of arrangements, 70, rue Jullien, Vanves, Seine.

Dr. Verger and Dr. Mauriac have reported four cases in which oral vaccination against typhoid, adopted preventively, was followed by typhoid. The periods elapsing between the final vaccination and appearance of the typhoid were 24 days, a few hours, eight days, and eight days.

The chairs of bacteriology and of experimental and comparative pathology at the Paris Faculté de Médecine are vacant. New appointments will soon be made.

The Conduct of Medical Practice.

XXV.—COVERING.

OF the duties imposed upon the General Medical Council by the Medical Acts, the disciplinary procedures against members of the profession convicted of unprofessional behaviour are the most difficult of comprehension by the public. And this is regrettable because the actions taken are taken entirely in the public interest. The offences, whose punishment is most frequently commented upon, may be grouped under improper advertisement and improper association with unqualified practitioners, and here the measure of impropriety must be estimated by the Council in accordance with its public duties, but for professional reasons, the force of which will not appeal always to the layman ; and, if a particular case attract the attention of the lay press, it is sadly true that a large number of newspapers take the invariable line of assuming that hardship has been done, while ill-informed persons, often with much ability, take a pleasure in describing the Council as tyrannous. Further, as medical men themselves read daily papers, and meet the promoters of the agitations, the reiterated criticisms of the Council may have their effect upon them, if they are not conversant with the actual facts. When this occurs immediately the criticisms of the Council become more bitter, because it appears that the professional standards employed to protect the public do not give satisfaction to professional men ; in short, those who regard the maintenance of professional standards as inimical to the public welfare view with satisfaction what they regard as a division of the medical forces.

WHAT IS COVERING ?

While far more sympathy is always manifested by the lay press for the medical man who is removed from the professional roll for advertisement, it occasionally happens that the circumstances where a practitioner loses his professional status for association with unqualified healers attracts public attention. This has happened, for example, in the case of Dr. Axham, because the unqualified man with whom he entered into intimate relations has received a knighthood while Dr. Axham's punishment for having entered upon those relations has not been relaxed. If, however, the story is considered from the beginning, it will be seen, first, that the Council had little or no option when they removed Dr. Axham's name from the Register, and secondly, that the method of restoration does not depend primarily upon the Council. Under the Medical Act of 1858, the Council is enjoined, at its discretion, to delete from the official roll the names of medical men whose conduct in professional respect is derogatory to accepted standards. To ensure that medical men shall not err through ignorance, the Council issues warnings, and among these one has appeared pointing out that association by a qualified medical man in medical practice with an unqualified person would render the medical man subject to penalty. Dr. Axham was associated in practice with Sir Herbert Barker—then Mr. Barker—who treated patients without possessing statutory medical qualifications, and the association was not denied. The circumstances were brought before the General Medical Council by the Medical Defence Union, and the Council finding the offence proven—it was not denied—decided to remove Dr. Axham's name from the Register unless he terminated his arrangement with the unqualified man. Dr. Axham then preferred to maintain the existing position, but he is now anxious to re-obtain registration. Being of advanced age, there is no doubt that he is no longer committing the offence for which he had to answer; the position of the Council, however, is that only qualified persons can be entered on the Register. Now Dr. Axham has lost his qualifications, for his diplomas were taken away from him by the Royal Corporations which had previously granted them in response to examinations. Unless and until the diplomas are restored the Council has not the power to act in the way it is insisted upon in some quarters that it should. It can be understood readily enough that this point might not be clear to the laymen who have attempted to advance the cause of Dr. Axham by abuse of the General Medical Council, but it is a little surprising to find medical men equally ill-informed as to the Medical Acts and as to the constitutional position and duties of the General Medical Council. On the general need of action by the disciplinary body of the profession against covering there cannot be two opinions, for if a man who is not qualified can practise as a doctor through association with one who is qualified, the Register ceases to protect the public against irregular practice. Again, to the question of whether a particular unqualified person can have exceptions made in his favour there can be but one answer—any exception would frustrate the whole of disciplinary procedure.

Ancillary Medicine.

Medical men who are careful to help in the maintenance of professional standards, and who are rightly jealous of the privileges conferred upon them in return for a strenuous and lengthy training, have many of them recognised, and recently with increasing force, that there are certain quasi-medical services, ancillary to scientific medicine, which are rendered properly by those without medical qualifications. The public can take advantage of such services, if that is desired, in a way that is of the greatest use to them, if the services are given upon medical advice as the need arises. There is then no doubt that the public obtains the assistance in response to medical advice, persons who do not need the particular treatment are not mulcted of fees, cures for non-existent conditions are not bruited abroad, specifics for cancer are not made the medium of false hopes, and lastly real benefit is obtained through the rightful exercise of special attainments.

Correspondence.

"Audi alteram partem."

THE EXTRINSIC ORIGIN OF CANCER.

To the Editor of THE LANCET.

SIR,—I have been greatly interested in Prof. Blair Bell's noteworthy paper on the Specific Character of Malignant Neoplasia, published in your issue of Nov. 14th. I believe he has made a contribution to our knowledge of cancer that will prove of very great value.

At the Memorial Hospital in 1915, following the lead of Loeb of St. Louis, we made an extensive experimental study of the effects of colloidal copper upon various types of malignant disease. However, the effects were so slight that we abandoned the method after several months' trial. Evidently Prof. Bell has proved that the inhibitory action of colloidal lead is much more marked than that of colloidal copper. His striking success in a considerable number of cases is of the utmost interest and importance. If these successful results prove permanent, as seems to be true in a few cases at least, and the method can be carried out without too high a mortality, we shall have added to our present very limited means of controlling cancer the only systemic method of attacking malignant tumours—with the exception of the administration of the mixed toxins of erysipelas and *Bacillus prodigiosus*, the value of which is restricted chiefly to sarcoma.

The larger part of Prof. Bell's paper is devoted to a discussion of the nature of cancer which, he believes, is far more important than a study of the specific cause of the disease. To quote him: "It is the result rather than the cause, as I hope to show, that is important, for undoubtedly malignant neoplasia is a specific process, but that is not to say that because a process is specific the cause must also be." He believes that the results of his method of treatment with colloidal lead strongly support, if they do not actually prove, his theory of the cause of cancer—i.e., that "malignant neoplasia in the human subject is a biological atavism," or, in other words, that the disease is due to intrinsic causes.

I do not believe that the rapidly accumulating evidence in favour of the extrinsic origin of cancer that has been presented within the last year by Glover, of Toronto and New York, by Young, of Edinburgh, by Nuzum, of Chicago, and last and most important, perhaps, of all, by Gye and Barnard, of London, can be so easily ignored or cast aside. The clinical evidence in favour of the extrinsic origin of cancer is, I believe, even stronger than the laboratory evidence. This clinical evidence was outlined at the annual meeting of the American College of Surgeons in October, 1924, in a symposium devoted to a discussion of Nuzum's paper.

I believe that Prof. Bell's success with the colloidal-lead method instead of supporting his view that cancer is of intrinsic origin actually furnishes another and very strong link in the chain of evidence in favour of the extrinsic origin of cancer. Assuming malignant tumours to be of extrinsic origin, or due to some micro-organism or virus, it would be the most natural thing to expect such micro-organism or virus to be influenced by chemical changes in the body fluids or by some chemical substance introduced by intravenous injection. We could ask for no better analogy than the effect upon syphilitic tumours caused by the introduction of salvarsan.

I can find nothing in Prof. Bell's experiments or results to confirm the belief expressed by himself that "causes are as nothing in comparison with the importance of the realisation that malignant neoplasia is a specific process of the nature, and subject to the control I have described."

Whatever be the final solution of the great issue, whether the theory of the extrinsic or intrinsic origin of cancer be the correct one, we should do nothing to discourage further research upon the problem; for the greatest hope of ever controlling the disease or of lowering its steadily increasing mortality rests upon the discovery of a specific cause.

I am, Sir, yours faithfully,
New York, Dec. 5th, 1925. WILLIAM B. COLEY.

PROFESSIONAL CRITICISM OF THE GENERAL MEDICAL COUNCIL.

To the Editor of THE LANCET.

SIR,—The very interesting leading article in your last issue deals adequately enough with public misapprehensions as to the constitution and functions of the General Medical Council, but, I would venture to suggest, fails to appreciate the whole of the professional case against this tribunal. Possibly you had intended to deal with these on another occasion, but in any case I should be glad if you would permit me a few remarks on the subject.

"It is not enough," you say, "that justice should be done; it is essential that it should seem to be done." It is very difficult from the information supplied by the medical press to form any definite view as to whether justice has or has not been done. In the first place there is a complete absence of that valuable précis—the judge's summing up. The charge is stated to be proved—i.e. the defendant is found guilty of infamous conduct in a professional respect. But no information is available as to exactly which of the alleged actions can be regarded as satisfactorily established. For example, was Dr. Lloyd at fault in permitting publication of his views (if he did so) or in accepting patients directed to him in this manner (if he did so, for none but the members of the G.M.C. know what facts were considered proved) or did the conjunction of the two create the offence? Secondly, we are never told what the penalty is intended to be—erasure of a name for a few months, or years, or for ever. Many members of the profession will be surprised to find restored to the Register the name of a gentleman who seems to have deliberately courted expulsion and who has not, so far as any one of your general readers can be aware, modified his attitude or purged his offence.

Those acquainted with the actual procedure of trials know that the mere physical circumstances and general atmosphere impose a definite hardship. I have commented elsewhere on the jury's letter-writing habits and would add that, if the jury must remain at 40 or thereabouts, it would be the barest justice to so arrange them that the defendant and his counsel might have them all properly in view. Nor is it desirable that counsel should be obliged to pause from time to time in his remarks until he may have the attention of the court—as certainly happens now.

It is sometimes said and thought that the G.M.C. is both accuser and judge. There is not lacking some ground for this misapprehension. His Majesty's judges administer a law made by others, the G.M.C. administers a law made by itself—the law of warning notices. This law is of a very general character and it is difficult for a defendant to argue that he has not infringed a law of whose detailed implications he cannot well be aware. Indeed, it may well happen that he will not learn the law applicable to his case until he has already been convicted, and he cannot altogether be blamed if he feels that the law may have been made to fit his case—especially if that case be some exposition of the modern art of advertising not hitherto brought to the notice of the G.M.C. And anything approaching an atmosphere of informality will certainly much increase any feeling of grievance which he may experience.

Then, again, it is known to those who have considered the matter that the G.M.C. may have great difficulty in ensuring that proper cases be brought before it. The Registrar receives from members of the profession press cuttings and other information. He cannot bring cases before the G.M.C. unless someone will prosecute. Potential prosecutors are few and willing prosecutors fewer still. Yet the facts brought to his notice and perhaps to his alone may clearly call for action. What is he to do? What in fact does he do? I will not answer this question, but I think it will be seen that prosecutor and judge may be forced into a juxtaposition very disagreeable to both of them.

This difficulty of a prosecutor sometimes seems to lead to a rather curious selection of cases. For example, where a doctor has appeared as co-respondent in a divorce case, it is often possible for a husband so inclined to secure his appearance before the G.M.C. On the other hand, if the husband does not know what is possible or is disinclined for action, the erring doctor may continue in practice and on the Register. The crime may be the same, but whether just retribution shall follow depends on chance and not on the G.M.C. This, I suggest, inevitably detracts from the dignity and status of that tribunal.

Finally, I would draw attention to the very small representation on the jury of those who can be considered peers of the accused. Those who experience in their daily lives the many difficulties and complexities of general practice are in a small minority. Yet, if professional standards of what is infamous are to adapt themselves to changing times, it is these very persons who are best able to judge of what adaptations are properly admissible. The majority of the G.M.C. cannot so easily judge from the standpoint of a life which they have never shared. A certain loss of touch with realities seems to be shown by the warning notice and other pronouncements about certificates. National Health Insurance is so administered that perhaps the majority of practitioners give with considerable frequency certificates which, although false, seem to be necessary if patients are to receive the benefits due. There is also a frequent certificate which requires the doctor to certify that he has seen all the children of so-and-so alive on this date. It may be that one of the children is not at home; it is seldom that the children are produced for inspection. Every circumstance in both cases conspires to prompt the doctor to an action which, in 99·9 per cent. of cases, is no more fraudulent or unethical than the subscription of "Yours sincerely" to an entire stranger. The G.M.C. does not seem to be aware of this particular source of trouble in medical practice. It is very prevalent and seems to increase. One would wish to see some sign that the distinction between technical inaccuracy and fraud or carelessness was better appreciated.

I must apologise for the length of this letter, but the matter is one of great importance to the profession. It is very necessary that the profession should feel confident in the G.M.C. I am less concerned about the public at the moment, the case for the public would follow different lines. It will be seen that there is a good deal which might be remedied without any alteration of the law. I do not impute any blame to the individuals who compose the G.M.C. except in so far as they have permitted a regrettable informality where a man's livelihood is at stake. But I and many others will be justified in imputing blame if we feel that no attempt is made to meet honest criticisms, and it is to avoid that unwanted justification that I have written at some length.

I am, Sir, yours faithfully,
Sevenoaks, Kent, Dec. 18th, 1925. GORDON WARD.

AN APPEAL FOR HUMAN EMBRYOS.

To the Editor of THE LANCET.

SIR,—We are in process of forming here a collection of serial sections of human embryos which will be available for study by all competent investigators. No reference collection such as we contemplate exists anywhere in England. It can only be got together through the active coöperation of medical men in practice, and we accordingly appeal to them for aid in the collection of the material. Year by year hundreds of specimens are wasted simply because the medical men into whose hands they fall do not realise that there is any demand for them, or that they are of value for embryological purposes. Our knowledge of human development and of the processes and conditions that result in abnormal development is still very incomplete, and it is only by the study of properly preserved specimens that the blanks in our knowledge can be filled up. Abundant human material of the kind we want is really available, and all that we ask is that such specimens as may from time to time come into the hands of practitioners should be preserved and sent to us, together with such clinical data as may be available.

We wish particularly: (1) *Embryos* passed in abortion, together with the membranes and decidua; where no embryo is apparent, the decidual fragments should be carefully preserved. (2) *Tubal pregnancies*, if possible unopened. (3) *Pregnancies in utero*, where the entire uterus is removed for surgical reasons; in such cases, the uterus should be opened by a median incision along the anterior wall and should then be placed in a large vessel filled with 10 per cent. formalin. (4) Under favourable conditions, the *uterus* and *ovaries* from P.M. subjects. (5) *Curettings* from cases where one or more periods have been missed. (6) *Stillborns*, particularly abnormal subjects.

Preservation of Specimens.—The most convenient preserving fluid is 10 per cent. formalin (ordinary formalin, 1 part, water or preferably normal saline, 9 parts). It is essential that specimens should be put into *plenty* of the formalin solution *as soon as possible* after they are obtained and that the solution should be changed for fresh after 24 hours. When forwarding the specimen, the bottle should be completely filled with the fluid; this prevents damage to the specimen through shaking.

We are prepared to send suitable bottles filled with preserving fluid, in containers for posting, on receipt of a post-card, or when the specimen is large, to arrange for its collection in the London area. The clinical data relating to the specimen are of great value and should be sent with it. We will send the practitioner a short report immediately on receipt of the specimen, and later on a more detailed report should it be desired. It is only by enlisting the help of practitioners in preserving such specimens as turn up in practice that we can hope to build up a really representative collection of human embryological material.

Specimens should be sent to the undersigned, Department of Embryology, Institute of Anatomy, University College, Gower-street, London, W.C. 1.

I am, Sir, yours faithfully,

Jas. P. Hill,

Dec. 17th, 1925. Professor of Embryology.

MASSAGE OF THE MIDDLE EAR.

To the Editor of The Lancet.

Sir,—In reference to your annotation upon Massage in the Treatment of Middle-Ear Deafness, it may interest your readers to know that I have, during the past 30 years, made use of this treatment in many forms, from the primitive Siegle speculum and its off-shoot the Delstanche otomasseur to various kinds of instruments worked by hand, water-power, or electric motor. As you very wisely point out, their effect is mostly upon the more mobile parts of the membrane and ossicles, and they have little, if any, influence upon adhesions or upon ankylosis of the ossicles of long standing. Some years ago I tried pneumatic otomassage in selected cases after mobilisation of the malleus, or following such operations as exploratory tympanotomy with severance of adhesions. The results were disappointing. In no case have I ever found the pneumomasseur in any form to have other than transient effects, and I am of opinion that when this temporary improvement occurred it was due to the equally transient hyperæmia induced.

Judging by a recent symposium in the United States, however, it would appear that most otologists are agreed that vibratory massage of some sort offers the best chance in the treatment of chronic middle-ear deafness. The whole question lies in the nature of the massage to be employed. With the instruments referred to the movements are too coarse to be of any real value; what is required is a movement of extremely short wave-length. The only instrument that I know which furnishes such a movement is the electrophonoïde of Dr. Zünd-Burguet. This method of treatment, so unfairly criticised by British otologists until G. C. Cathcart's paper appeared in your columns,[1] is giving excellent results in my hands. It is a method of auditory massage which is eminently adapted to the ear because it is performed by sound waves, which are obviously the proper physiological stimulant for the hearing organ. As Dr. Zünd-Burguet points out in his "Principes d'Anacousie," the method is both pedagogic and therapeutic. On the one hand, it teaches the patient to listen and to hear; on the other, by its local action in causing hyperæmia, it stimulates the tympanic mucosa and intratympanic muscles, and causes a regeneration of tissues, analogous to the action of massage upon a wasted, stiffened limb, whereby the ossicular joints are freed and adhesions stretched. In one case recently a young lady, whose hearing was reduced to R. = 6 in. and L. = 0 for the whisper and R. = 4 ft. and L. = 1 ft. for the ordinary voice, and whose case was pronounced to be hopeless by two well-known provincial otologists, improved after 12 sittings to R. = 4 ft., L. = 1 ft. for the whisper and over 20 ft. R. and L. for the low voice. After the full 30 sittings her paracusis Willisii disappeared, and she could hear everything in a theatre from the middle of the stalls.

I have no experience of Dr. Braun's new method mentioned in your annotation, but I would venture to suggest that the Zünd-Burguet method is superior and far less uncomfortable than massage of the nasopharynx and Eustachian tubes by wool-tipped probes.

I am, Sir, yours faithfully,

Macleod Yearsley.

Wimpole-street, W., Dec. 19th, 1925.

The Services.

ROYAL ARMY MEDICAL CORPS.

MILITIA.

Maj. (Bt. Lt.-Col.) W. H. G. H. Best retires on attaining the age limit, and retains his present rank.

TERRITORIAL ARMY.

General List.—Lt.-Col. (Bt.-Col.) F. Hawthorn, having attained the age limit, is retired, and retains his rank with permission to wear the prescribed uniform.

Lt.-Col. J. Barkley and Majs. L. A. Mackenzie, A. Coleridge, W. S. Richardson, and L. J. E. McHugh, having attained the age limit, relinquish their commns. and retain their rank.

General Hospitals.—Maj. C. A. S. Ridout, having attained the age limit, relinquishes his commn. and retains his rank.

Supernumerary for Service with the O.T.C.—Maj. W. J. A. Laird (Res. of Off.) to be Maj. and to command the Med. Unit, Belfast University Contingent Senr. Div. O.T.C.

TERRITORIAL FORCE.

General List.—Maj. (Prov.) H. Forrest is confirmed in his rank.

ROYAL AIR FORCE.

E. A. Aslett and H. M. Levy are granted short service commissions as Flying Officers, for three years on the active list.

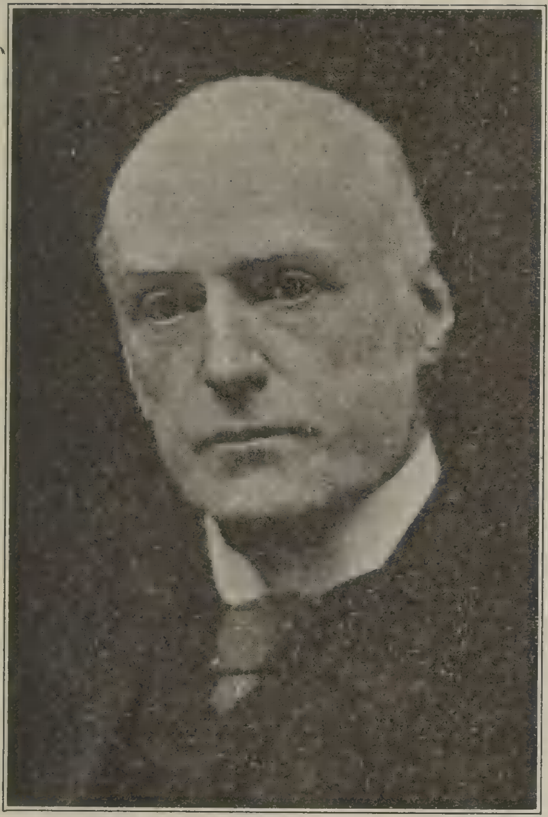
Kingston-on-Thames Hospital.—The board of guardians have decided to proceed with a scheme for the extension of Kingston and District Hospital and the erection of a nurses' home, at an estimated cost of £100,000.

Obituary.

SIR RICHARD DOUGLAS POWELL, BT., M.D., F.R.C.P. LOND., K.C.V.O.,

PHYSICIAN-IN-ORDINARY TO H.M. THE KING; CONSULTING PHYSICIAN TO THE MIDDLESEX AND BROMPTON HOSPITALS.

WE announced last week the death after a short illness of Sir Richard Douglas Powell, which occurred on Dec. 15th at his residence in London in the eighty-fourth year of his age. He had for many years been an outstanding and deeply respected leader of the medical profession. His broad outlook on medicine in general, his attainments in special clinical fields, and his sincere regard for the best ideals before the profession which he adorned, had made of him in the medical world, as in the world without, a veritable type of the wise consulting physician.



SIR RICHARD DOUGLAS POWELL.

Richard Douglas Powell was born at Walthamstow in 1842, being the second but only surviving son of Captain Scott Powell, an officer in the Royal Welsh Fusiliers. Educated privately, he received his medical training at University College, London, and graduated in the University of London just 60 years ago as M.B., proceeding to the M.D., which he took with honours in the following year. Quite shortly afterwards he was appointed assistant physician to the Brompton Hospital for Consumption and Diseases of the Chest, and as active member of the staff and consulting physician he served the hospital for 57 years.

His first position on the staff of a London general hospital was at Charing Cross, where he was elected assistant physician and lecturer on materia medica in 1871, a post which he occupied until appointed in 1878 assistant physician at Middlesex Hospital. Here he became full physician three years later, and during 30 years was a mainstay of the scientific, educational, and charitable activities of the institution.

In three different directions throughout his long professional life Douglas Powell occupied a prominent position to the satisfaction of all who worked with or under him. He was a great Court physician; he was a great President of the Royal College of Physicians of London, and he was a great clinician. His introduction to the Court was due to the high opinion which Sir William Jenner had formed of him in the early stages of his career when he was filling the junior posts at University College Hospital. The connexion between his distinguished master and Powell was an intimate one, and led to his appointment as physician-in-ordinary to Queen Victoria at a comparatively early stage in his professional career. He became at once an acceptable figure at Court, where no doubt his distinguished and graceful personality were appreciated in common with his wide range of ability. He attended Queen Victoria in her last illness, and subsequently was physician-in-ordinary successively to King Edward VII. and to the present King.

His connexion with the Royal College of Physicians of London began with the Membership, which he took in 1867. He was elected Fellow in 1873, served as Senior Censor in 1902, and as President for five years—namely, 1905 to 1910. He is on all accounts allowed to have been a successful President, maintaining the dignity of the office, and sparing no pains to insure that the College should take an intimate part in professional progress.

As a physician he was a leading figure not only in London, but in all medical society at home and abroad for more than half a century. His early association with Brompton Hospital dictated the fact that it was as a specialist in pulmonary and cardiac conditions that he became most widely known, but throughout the greater part of his professional life his work at the Middlesex Hospital enabled him to maintain legitimately the position of an all-round man, and to look upon the large and particular branches in which he may be said to have specialised as a chapter, if a very large and far-reaching one, in the general story of pathology. It goes without saying, therefore, that he spared no pains to keep abreast of medical technique and medical literature. His work upon the physics of the chest, which appeared as long ago as 1875 in the Transactions of the Medical and Chirurgical Society, showed both the general and special knowledge which he had already acquired.

Thus Douglas Powell, both in personality and in achievement, looms large in the medical history of his generation, and there will be none to cavil at the high measure of success he secured. At a time when specialism was less the rule than at present, he was at once an accomplished general physician and a specialist of world-wide renown. His long association with the Brompton Hospital probably served to determine his special bent towards the study of diseases of the lungs and heart. His was an eminently practical turn of mind, and it is therefore not surprising that his interest was more especially directed to the clinical features of these diseases and particularly to their treatment. His well-known "Text-book of Diseases of the Lungs," was one of the earlier special monographs. That it has fulfilled a useful purpose is shown by the fact that it has reached a sixth edition, in the preparation of which Sir Percival H.-S. Hartley has collaborated. It is worthy of note that the careful clinical and pathological study of disease by the generation of physicians of which he was so distinguished a representative rendered possible the modern advances which have been achieved by instrumental and experimental methods and by the more scientific means of investigation now available.

A mere enumeration of the more important of his contributions to the study of diseases of the lungs and heart affords a striking testimony not only to his industry, but to his profound acumen in these matters.

His earliest communication to the Royal Medical and Chirurgical Society, on Some Effects of Lung Elasticity in Health and Disease, discussed the problems of the negative pressure in the pleural space and its effects in a way which indicate the new purview of diagnosis. He subsequently read papers or published notes on pulmonary tuberculosis, pleuritic effusion, pneumothorax, and hæmoptysis. He delivered the Lumleian lectures before the Royal College of Physicians on Principles which Govern Treatment in Diseases and Disorders of the Heart. These lectures were published in THE LANCET and are a model of what such disquisitions should be—they were clear, informatory, based on constructive work and not on routine.[1] In his Harvein Oration, delivered at the same College in 1914, he dealt with the principal Advances in Knowledge Regarding the Circulation and Attributes of the Blood since Harvey's Time. The oration was at once simple, eloquent, and learned; the résumé of modern knowledge as to the influence of the internal secretions and the defensive attitude of the blood, with which it closed, being a model of the attitude which a great healer should take towards progressive developments in his science and art. Other subjects which engaged his special attention and interest were angina pectoris, aneurysm of the aorta, and mediastinal tumour, on all of which he contributed articles to "Reynolds's System of Medicine"; in the last his summary of the pressure signs of aneurysm was singularly clear and practical. His style was cultured and polished, without being pedantic. His clinical lectures were always worth listening to. They often included descriptions of cases rather in the manner of Sir Thomas Watson or Trousseau, with admirable practical hints in regard to treatment. Since the war he delivered an emeritus lecture at the Middlesex Hospital on the Problems of Blood Pressure, which showed that he retained his keen interest in the problems of diseases, and that he was still keeping in touch with the modern advances.

His tenure of the post of the President of the Medical and Chirurgical Society was marked by the successful carrying out of the scheme for amalgamation of the metropolitan societies which had been ventilated 12 years previously by Sir John MacAlister, with Sir Andrew Clark behind the movement. The scheme received the approval of a large group of leaders of the medical profession within and without the metropolis, but the interests involved were not always identical, and there is no doubt that the universal respect in which Douglas Powell was held, and the tactful manner in which any negotiations which fell to his share were carried out, counted enormously in the institution of the Royal Society of Medicine.

We have received a tribute to him from one who had known him for over 30 years, and been in close association with much of his work. The letter runs: "Sir Richard Douglas Powell was a very reserved man, but to one who was privileged to work with him and for him for many years he revealed himself as one of the most kind-hearted and generous of men as well as the dignified and courteous personality that all could observe. His courtesy was of deed as well as of word, and was the expression of a beautiful and unselfish character, and not a veneer. His kind-heartedness was displayed in his readiness to help any who asked his advice, and he entered into their difficulties in such a way that his counsel became of value because so well directed. At the same time his consideration for those who assisted him was marked; indeed, he always seemed surprised and even grateful for the smallest service rendered to himself. His watchwords were self-constraint and self-control, and he acted up to his principles. Good-tempered, he kept his temper completely under control save where occasionally it flashed out in scorn of mean or self-interested actions, or of slackness, of which he was quite intolerant. For the rest his knowledge of human nature and its foibles was so wide that his sympathy was always extended to those who were doing their best, whatever the accomplishment; and though he could, and would, rebuke where he considered this was deserved, the rebuke would be so tempered as to stimulate rather than to humiliate. His strong character made it impossible to turn him from a course of action while he was convinced that it was the right one, an aspect of him which was better known to his intimate circle than without, where his graciousness of manner obscured to superficial observation his determination."

To him honours came in profusion. His Court appointments have been mentioned. He was an Hon. D.Sc. in the University of Oxford, an Hon. M.D. in the University of Dublin and the Royal University of Ireland, Aberdeen and Birmingham Universities gave him an LL.D., and he was an Hon. F.R.C.P. Irel. He was created a baronet in 1897 and appointed K.C.V.O. in 1901.

Sir Richard Douglas Powell married in 1873 the second daughter of the late Sir John Bennett, by whom he had three sons and two daughters. He is succeeded in the baronetcy by his eldest and only surviving son, Lt.-Col. Douglas Powell, C.B.E., the two other sons having given their lives for their country, the second son being killed in action in the South African War and the youngest one dying of wounds in Mesopotamia in 1916. The tragedies tried the father deeply, but his patriotic courage suppressed resolutely his deep sufferings. He married secondly in 1917, Edith Mary, daughter of the late Mr. Henry Wood, of Cleveland-square, who survives him, and to whom we tender every sympathy.

EDWARD FRANCIS PALGRAVE, M.R.C.S. ENG.

Dr. E. F. Palgrave, who died in London on Dec. 13th, was son of the late William Gifford Palgrave, of the Foreign Office Service, and was born at St. Thomas's Island in 1875. He was a nephew of Francis T. Palgrave, professor of poetry at Oxford, of Sir Reginald Palgrave, Clerk to the House of Commons, and of Sir Inglis Palgrave, the well-known economist. He was educated at Clifton where he gained an entrance exhibition, entered St. Bartholomew's in 1892, qualified in 1897, and was appointed by Sir William Church as his house physician. After passing through the Tropical School of Medicine, he practised at Sunbury, Middlesex, for six years, after which he obtained an appointment in the school medical service of Middlesex, where he remained for four years. In 1912 he was appointed to the school medical service of the London County Council, where his ability soon manifested itself; while pursuing his routine duties he made several reports which attracted attention, in particular dealing with the causes of malnutrition in school-children.

Dr. Palgrave joined the Royal Army Medical Corps in 1914 and was put in charge of the Officers' Hospital at Havre for 12 months when, owing to the absence of many senior officers, the need for some one with exceptional clinical knowledge was experienced at the headquarters of the London County Council, and he was withdrawn from the school medical service in order to work at the head office. New administrative duties allotted by statute to the Council necessitated an increase in senior officers, and in 1920 Dr. Palgrave was promoted to the office of divisional medical officer. In this capacity he directed the administration of the Midwives Act and the sections of the Children Act dealing with children below school age. He also took a large share in the new and responsible work connected with the public provision for the treatment of venereal diseases.

For the past 18 months his health had been visibly failing, nevertheless he made heroic efforts to carry on his duties. "Palgrave's geniality and unselfishness," writes one of his colleagues, "had endeared him to all who worked with him, while his clinical acumen and administrative ability had earned their deep admiration and respect."

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Bethlem Hospital Bill.

ON Wednesday, Dec. 16th, a motion was agreed to in the House of Commons carrying over to next session the Bethlem Hospital Bill. Mr. J. F. **HOPE**, Chairman of Committees, stated that the Bill had been objected to from time to time, and he had adjourned it in the hope that a settlement might be arrived at. No settlement had yet been reached, but he had every hope that if the measure was carried over to next session a settlement might be arrived at. On Friday, Dec. 18th, in the House of Lords a similar order was agreed to.

Asylum Officers' Superannuation.

Mr. **TAYLOR** presented a Bill in the House of Commons on Friday, Dec. 18th, to amend the Asylum Officers' Superannuation Act, 1909, which was read a first time.

HOUSE OF COMMONS.

WEDNESDAY, DEC. 16TH.

Vaccination Exemptions.

Mr. **GROVES** asked the Minister of Health whether, in view of the fact that the ratio of exemptions from vaccination was progressively increasing and the ratio of small-pox deaths correspondingly decreasing, he would consider legislation to amend the obligatory vaccination laws and put them in such a way that persons who themselves desired or desired their children to be vaccinated should apply for such publicly assisted service, not, as at present, that those who desired to be exempt must apply.—Mr. N. **CHAMBERLAIN** replied: I am not prepared at present to consider the question of legislation on the lines suggested by the hon. Member.

Deaths from Small-pox.

Mr. **GROVES** asked the Minister of Health if he would present statistics to show the number of persons in England and Wales who, in the ten years ending with 1921, died of small-pox although admittedly successfully vaccinated; the number of persons who died of small-pox in the same period and were classified as not vaccinated; the number classified as doubtful who died of small-pox; and the percentage of births vaccinated in that period of ten years.—Mr. N. **CHAMBERLAIN** replied: The records in the possession of my department show that, of the 122 persons who died of small-pox during the ten years ending with 1921, 43 had been vaccinated, 59 had not been vaccinated prior to exposure to infection, and in 20 instances the vaccinal condition was doubtful. The 43 vaccinated cases included no person under the age of 12, 4 persons between the ages of 12 and 25, and 4 between the ages of 25 and 35, the remainder being in each case over the age of 35. The records show that only 4 of the vaccinated cases had been revaccinated, the ages of these persons being 25, 35, 58, and 64 respectively. Of the 59 unvaccinated persons, 26 were under the age of 12, 18 between the ages of 12 and 25, 9 between the ages of 25 and 35, and 6 over the age of 35. The percentage of births vaccinated during the period in question was 43·5.

Sanatorium Treatment for Pensioners.

Mr. **PIELOU** asked the Minister of Pensions the amounts spent by his department upon sanatorium treatment for pensioners suffering from tuberculosis during the last five years.—Major **TRYON** replied: The aggregate expenditure of my department upon the treatment of pensioners in sanatoriums during the five years ending March 31st, 1925, was approximately £2,500,000.

Duties of D.C.M.S.

Mr. **ROBINSON** asked the Minister of Pensions what area deputy commissioners of medical services were responsible for more than one area as constituted under the War Pension Act of 1921, and in what town was the office of the area deputy commissioner of medical services situated; and what were the areas for which area deputy commissioner of medical services was responsible.—Major **TRYON** replied: Each of the deputy commissioners of medical services is responsible for more than one area with the exception of the deputy commissioners stationed at Aberdeen, Gloucester, Leicester, Belfast, and Bristol.

Final Pension Awards.

Mr. **DAVID GRENFELL** asked the Minister of Pensions whether, seeing that of 6239 appeals heard against final awards made by the Ministry 3381 were successful, he would take steps to ensure that more careful consideration of the men's disabilities was given by the medical final awards board and awarding officers, so that men were not under assessed and/or their pensions terminated without sufficient cause.—Major **TRYON** replied: I would remind the hon. Member that about half the cases in which the appeal is regarded as technically successful are cases where the Ministry's assessment was not modified, but finality of the award was for the time being set aside for further consideration. The existing instructions of the Ministry provide for the fullest consideration of all cases and a final award is not made where the prognosis of the case is doubtful or there is prospect of deterioration.

Pensioners and Chronic Chest Trouble.

Mr. **RADFORD** asked the Minister of Pensions the approximate number of ex-Service men in receipt of pension for chronic chest trouble; and would he consider the advisability of providing establishments for such cases in parts of the country with a salubrious climate where these men, particularly those from the industrial areas, might proceed for a period during the winter months when they suffered most severely from their home climatic conditions.—Major **TRYON** replied: About 59,000 men are in receipt of pension in respect of a disablement arising from one or other form of chest affection. Rather more than half the total number are cases of pulmonary tuberculosis, for whom treatment is by statute the concern of the local health authority acting under the Ministry of Health. As regards sanatorium provision for these cases, I understand that the climatic factor is always considered. Cases, however, of chest affection other than tuberculosis are, where necessary, provided for in Ministry institutions situated in various parts of the country, and in the event of a change of climate being essential in any individual case transfer from one hospital to another can be effected. The results of treatment of these cases in Ministry institutions do not, I am advised, indicate any need for the setting up of further institutions in other localities.

School-children and Dental Treatment.

Colonel **DAY** asked the President of the Board of Education whether his attention had been drawn to the fact that of 2,000,000 school-children inspected in 1924, 67 per cent. of whom were found to be in need of dental treatment, only 55 per cent. received such treatment; and what action was contemplated in order to deal with those not receiving dental care.—Lord E. **PERCY** replied: I assume that the hon. Member refers to the statement on p. 66 of the report of the Board's chief medical officer for the year 1924. As regards the second part of the question, this is one of the matters that local authorities have doubtless been considering in connexion with their programmes.

Ex-Service Men and Tuberculosis.

Mr. **PIELOU** asked the Minister of Health whether, in view of the fact that over 21,000 ex-Service men had died from tuberculosis as a result of their war service, he intended to adopt the recommendation of the Inter-departmental Committee of 1919 and expend the amount suggested for the purpose of increasing village settlements throughout the country.—Mr. N. **CHAMBERLAIN** replied: In the present financial circumstance of the country I could not contemplate expenditure on the scale which would be required to carry out the recommendation referred to by my hon. friend. I may, however, say that extensions and improvements of the two existing village settlements are now being carried out with Exchequer assistance and I shall not lose sight of the matter.

Value of Primary Vaccination.

Mr. **GROVES** asked the Minister of Health whether he could state the considered judgment of the medical advisers of his department with regard to the utility or otherwise of primary vaccination; and whether he contemplated any measures for the obligation to revaccinate quinquennially.—Mr. N. **CHAMBERLAIN** replied: The answer to the first part of the question is that, in the judgment of my medical advisers, primary vaccination is of great and amply-proved utility. The answer to the second part of the question is in the negative.

Ministry of Health and Small-pox.

Mr. **GROVES** asked the Minister of Health the reasons why the words about the tragedy of a widespread epidemic of small-pox being realised had been omitted at the end of the first paragraph in the 1924 edition of the Ministry of Health's pamphlet, No. 8, on the subject of small-pox and vaccination.—Mr. N. **CHAMBERLAIN** replied: The words in question were omitted in view of the general mildness of the type of small-pox prevalent in this country at the time the pamphlet was revised.

Protection against Diphtheria.

Mr. **DUNCAN** asked the Minister of Health whether the three nurses who contracted diphtheria while attending a case of that disease in the Brentford urban district in March, 1924, as mentioned on p. 55 of the Annual Report of the Chief Medical Officer of the Ministry of Health for the Year 1924, had been previously immunised against that disease in any way; and whether any of the cases proved fatal.—Mr. N. **CHAMBERLAIN** replied: The answer to both parts of the question is in the negative. I am, however, informed that one of the nurses, seven months before attending the case referred to, had received a dose of diphtheria antitoxin, but that this dose would not confer immunity for more than one month after it was administered.

Medical Services in Africa.

Dr. **SHIELS** asked the Secretary of State for the Colonies how much below establishment strength were the medical and sanitary services of Nigeria, Gold Coast, Sierra Leone, Kenya, and Tanganyika, respectively; what steps were being taken to fill the vacancies; and who was responsible for recruiting and selecting the required personnel.—Mr. **ORMSBY-GORE** (Under Secretary for the Colonies) replied: As regards the West African Medical Staff, at present there are 19 vacancies in Nigeria, 13 in the Gold Coast, and none in Sierra Leone. Nine selected candidates are receiving instruction in this country in tropical medicine and eight more will commence instruction in the new year. There are no vacancies in Kenya and only one in Tanganyika. The vacancies and terms of service are advertised regularly in the medical press, and the attention of the universities and teaching schools is drawn to these services periodically; while advantage is taken of the presence of senior medical officers on leave in this country to visit the medical schools and interest the students in the colonial services. Selection of candidates is made by the Secretary of State with the assistance of a small subcommittee containing two medical men of distinction who advise as to the suitability of candidates who are interviewed by them.

FRIDAY, DEC. 18TH.

Housing.

On the motion for the adjournment,

Mr. T. **THOMSON** raised the question of housing. He said that under the various Housing Acts there had been erected from 400,000 to 500,000 houses. It was a foolish idea to suppose that that had, or was likely to do away with the shortage which existed in 1919. As a matter of fact the houses which were required to meet requirements and overtake arrears since the Armistice was over a million. The complacent attitude of the Ministry of Health that they were not satisfactorily overtaking the arrears was not a view held by everybody. As the arrears amounted to 500,000 houses it would be another ten years before they could regard the position with equanimity. He was sure that the Minister could not be satisfied with the progress made, and he invited him to tell the House what he proposed to do to expedite building.

Sir **LESLIE SCOTT** said he found himself in agreement with a great deal which Mr. Thomson had said and he regarded that as symptomatic of the attitude of the House to the housing problem. To a great extent it was getting outside the arena of party politics. They had solved the broad problem of the supply of housing accommodation in the country, though he agreed with Mr. Thomson that they had not yet caught up, or anything like, to the point at which they ought to be and which they must use every possible endeavour to attain as soon as they could. Six years had now passed since the end of the war and the time had come when the slum problem, as a problem somewhat separate from the main housing problem, ought to be tackled in grim earnest. It was a problem which was vitally affecting the efficiency of the whole of our labouring population, and one which they could not afford to leave as it was without using every conceivable effort that either Parliament or the local authorities could possibly make to assist in its solution. A large proportion of the workers of each great city must be housed in more or less the centre, and they must find houses for these people in the centre. The medical officer of health for Liverpool, in his report for the current year, stated that in Liverpool there were at present approximately 2246 houses of the worst type—i.e., back-to-back houses—which were absolutely unfit for anyone to live in for a week. Yet they had been inhabited for years. In addition to that there were some 6000 houses, not back-to-back houses, which the medical officer described as "in such an insanitary condition in respect to structure and sanitary arrangements that they called for improvement." The difficulties in the way of slum clearance were roughly two: In the first place they had to rehouse the displaced population, and that had been in the years since the war the greatest difficulty because of the dearth of houses elsewhere. In the second place there was the cost of acquiring those parts of an unhealthy area which were not actually occupied by insanitary houses and of acquiring land elsewhere within the centre of the city to house the displaced residents during the period while their own area was under reconstruction. If they were going to rehouse on the cleared area anything like the density of population which they were displacing they could not put back small houses. The Act of 1924 and the circulars under the previous Act aimed at 12 houses to the acre, which was too low a number for practical purposes in a large city, much as they would like to attain to it. The only thing was to have large tenement blocks, such as those that have been erected by the London County Council. The practical question was how to make those large tenement blocks as much like real houses as they could. In Liverpool they were proposing to adopt a system of something in the nature of a clearing-house where they could invite the displaced residents to go temporarily while the area was being demolished and rebuilt. They could build the clearing-houses in large tenement blocks of the right kind so that when they were no longer needed as clearing-houses they could be used as permanent houses. A great many local authorities had been prevented from embarking on slum clearance schemes because the cost was prohibitive. There was need for the reconsideration of the whole financial question of the cost in regard to slum clearances. There must be some way of getting on with this question of slum clearances. Either they must tempt local authorities by additional financial assistance, or they must impose upon them greater responsibilities and the Minister must have greater powers to see that those responsibilities were carried out. There ought to be powers of compulsory requisition for the purpose of acquiring sites in connexion with rehousing. Greater powers of town planning and road construction might be given in connexion with large improvement schemes. Thirdly, in regard to such schemes there ought to be a provision for betterment. He thought that the House should ask that this problem should be tackled with a view to the introduction of legislation next session.

Lieut.-Colonel **FREMANTLE** said that they had got over most of their legislative difficulties in regard to housing and the main thing that they wanted now was good will. They must consider the distribution of housing from a radical point of view. The only ideal at which they ought to aim, the only solution of the problem in the long run, was the creation of new towns on properly selected sites according to schemes well thought out beforehand. They had to persuade factories to move out to such places as Welwyn, and if they did so the workers would be delighted to move out. They had just discovered that the Trade Facilities Act was available to assist factories to be moved out in this way. Let them start this new idea; they had the opportunity now.

Mr. N. **CHAMBERLAIN** (Minister of Health) said that in the five years period ending 1904, which was the peak period of house-building in this country, the average number built per year was 116,370 of all kinds of houses. In the years 1905 to 1909 the number was 102,706. The figures applied to England and Wales. From 1909 to 1914 the average was 60,648. If one compared that with the 159,000 odd houses built this year and bore in mind that this was a gradually rising figure, he though that the Mrs. Gummidge of the Liberal Party (Mr. T. Thomson) must take heart. They did not need any fresh legislation to get new houses; they were getting them at an increasing rate, and they might be satisfied that they were on the right road, because they were certainly eating into the arrears at a very considerable rate. Every year as some of the more remote places got their needs filled there would be labour and materials released which would come to the assistance of some of the blacker and more difficult spots where there was a great amount of arrears to be made up. They were also making some progress in slum clearances. In the 24 years from 1890 until 1914 only 43 local authorities put forward 71 schemes in all. But in the six years 1919 to 1925, 71 local authorities had submitted 92 schemes, of which 83 had been confirmed. There was also an enormous amount of repairs, alterations and renovations going on all the time. In urban areas alone in the last year for which the complete figures were available—namely, 1923—256,000 houses were made habitable after the service of statutory notices by local authorities. In addition there were a number of houses which were made fit by the urban authorities themselves. Another 253,000 houses had been made fit as a consequence of informal notices given to the owners by the local authority. Something of the same sort of thing was going on in the rural areas. In the same year 49,530 more houses were put into habitable conditions in rural areas under similar proceedings. As regarded the housing of the population in large centres, he did not see at the moment any alternative but to contemplate to some extent the erection of flats, possibly what were called high flats, in some of the more crowded areas to provide for those who found it necessary, or who desired, to live near their work. But they should not imagine that it would always be the case that people would desire to live near their work, nor should they put themselves in a position so that it would be impossible if conditions changed to make better provision for the future. The slum problem was a social as well as a building question. Some education was necessary in the case of some of the slum dwellers to enable them to appreciate surroundings so different from those to which they had been accustomed.

Mr. BALDWIN (Prime Minister) said that for some reason or another which he did not pretend to diagnose it was quite evident that the offer he made in Glasgow in September with a view to encouraging the building of houses in Scotland had failed in its effect. Whereas he had made an offer applying to 4000 houses, the burghs had put in for less than a quarter of the number proposed. The counties had not yet been in a position to advise the Government. In these circumstances he had to announce that the £40 special subsidy scheme lapsed. In its place the Government intended to proceed forthwith with the erection of 2000 houses by alternative methods. They proposed in the first place to utilise the Scottish National Housing Company. The Government would finance the development and take every necessary step to secure its accomplishment. The number of houses was not large and represented barely 1 in 50 of the estimated shortage to-day in Scotland. But he hoped and believed that it would give a push to enterprise in Scotland, whether it be private enterprise or enterprise on the part of the local authorities, so that they might assist in bringing what was in the way of becoming a national scandal in Scotland to an end.

Mr. STEWART (who was Under Secretary to the Scottish Board of Health in the Labour Government) said he would beg the Secretary of State for Scotland and the Board of Health, in the interest of the well-being of the country and its citizens, to prevent, as far as they could, the erection of tenements and above all the development of the room-and-kitchen house. In Scotland they had already 113,000 room-and-kitchen houses out a total of 235,000. In Glasgow they were spending in health administration more on the treatment of tuberculosis than Birmingham was spending on the whole of its health administration. It cost them a quarter of a million pounds to deal with the effects of tuberculosis. At the moment they were building a sanatorium that would cost them £500,000, to house 400 people after they had been lucky enough to contract tuberculosis. They would spend over £2 per week per patient to cure them, and then they would send them back once more, with the foolishness that was characteristic of the country in many respects, to the rooms-and-kitchens, and single apartments. In three months, in six months, in nine months they would be back again, and then at the end of five years, after all their money was spent, they would be dead, every one of them.

MONDAY, DEC. 21ST.

Opium Control in India.

Mr. THURTLE asked the Under Secretary of State for India whether the Government of India agreed at Geneva to allow an independent committee of the League of Nations to visit India to examine the control of the opium traffic.—Earl WINTERTON replied: Under the protocol to the Geneva Convention a commission will be appointed by the Council of the League of Nations to decide at the end of five years whether control in the signatory countries is sufficient to prevent completely the smuggling of opium from constituting a serious obstacle to the effective suppression of the use of prepared opium in those territories where such use is temporarily authorised. The protocol has been accepted by the Government of India.

DONATIONS AND BEQUESTS.—Mr John Buchanan Hinshaw, Woolton, Liverpool, after certain legacies and subject to a life interest, gave the residue of his property as to £500 to the Royal Infirmary, Liverpool, and as to £500 to the Bluecoat Hospital, Liverpool.—Mr. Henry Peech, of Ridgway, Wimbledon, Surrey, steel manufacturer, and of Sheffield, who left £107,388, left the greater part of that sum for "such charitable institutions or benevolent objects as he may name in any memorandum and subject thereto as his sister-in-law, Vera Millicent Peech, may select"; but £10,000 is to be paid to Lord Mayor Treloar's Crippled Homes and £5000 to the Sunshine Home for Blind Children, Chorley Wood.—Miss Ellen Jane Sandys, Hove, besides other bequests, left £500 each to the Royal Hospital for Incurables and All Saints' Convalescent Hospital, Eastbourne.—Mrs. Katherine Louisa Ricketts, of Exmouth, who left £13,036, gave £125 each to the British Home for Incurables at Streatham and the Royal Hospital for Incurables, Putney, and the residue of the property as to three-twentieths to the Homes for Aged Poor instituted at Kensington, Paddington, Hammersmith, Battersea, and Norwood in the year 1869; two-twentieths to the Exmouth Local District Nursing Association; six-twentieths to the Home for Incurables at Streatham; six-twentieths to the Royal Hospital for Incurables, Putney; and three-twentieths to the Seamen's Hospital, Greenwich.—Mr. Alfred Frederick Ikin, of Crewe, a brakesman in the employ of the L.M. and S. Railway, has left in his will £1000 to the Crewe Cottage Hospital, with the wish that a bed should be named the Alfred Frederick Ikin bed, in memory of his late wife and himself.

Medical News.

UNIVERSITY OF OXFORD.—In the recent examinations for the degrees of M.B. and B.Ch. the following candidates passed in the undermentioned subjects:—

Medicine, Surgery, and Midwifery.—Francis J. Bach, New Coll.; Leslie J. Barford, Queen's; Reginald H. B. Bettington, New Coll.; Vernon H. Brink, Hertford; Noel Chilton, Brasenose; Alan C. Gairdner, University; Stanford, Howard, Christ Church; Raymond Lewthwaite, Magdalen; Richard G. Mathews, Queen's; Charles W. Simpson, Balliol; David O. Williams, Jesus; Kathleen G. Norton, St. Hugh's; and Nancy B. Ockenden, Lady Margaret Hall.

Materia Medica.—Henry H. Aitchison, Brasenose; John C. K. Chilcott and Cuthbert L. Cope, Exeter; Alan W. Cubitt, Wadham; Samuel B. Davis, Non-Collegiate; John L. Glover, Queen's; Robert E. Havard, Keble; Ensor R. Holiday, Trinity; Harry E. Mansell, Pembroke; and André J. M. Melly, University.

Pathology.—Michael D. Bower, Trinity; Vernon H. Brink, Hertford; Cuthbert L. Cope, Exeter; Walter N. Dickenson, Pembroke; Otto Hooper, University; William H. Hudson, Brasenose; Robert Illingworth, Exeter; Arthur J. Leslie-Spinks, Oriel; Robert G. MacGregor, Worcester; Ripley Oddie, Oriel; David I. Rees, Exeter; Grace Batten, Lady Margaret Hall; and Rosaleen L. Graves and Constance I. Pattullo, Society of Oxford Home Students.

Forensic Medicine and Hygiene.—Reginald H. B. Bettington, New Coll.; Michael D. Bower, Trinity; Vernon H. Brink, Hertford; John C. K. Chilcott, Exeter; Noel Chilton, Brasenose; John H. Chitty, New Coll.; James A. Eyres, Lincoln; Eric L. Fothergill, Keble; Alan C. Gairdner, University; Kenneth A. Hamilton, Christ Church; Reginald A. Haythornthwaite, Keble; Stanford Howard, Christ Church; Thomas C. Hunt, Magdalen; Richard G. Mathews, Queen's; Frederick J. Sale, Christ Church; Samuel Segal, Jesus; Charles W. Simpson, Balliol; Arthur G. Wilson, Brasenose; Edward M. Wright, New Coll.; Margaret N. Jackson, Somerville; and Constance I. Pattullo, Society of Oxford Home Students.

UNIVERSITY OF CAMBRIDGE.—Mr. Joseph Barcroft, M.A., F.R.S., Fellow of King's College, has been elected to the Professorship of Physiology left vacant by the death of Prof. J. N. Langley. Mr. Barcroft gained first-class honours in the Natural Sciences Tripos, Part II., in 1897, with distinction in physiology. He won the Walsingham Medal in 1899 and the Gedge Prize for original observations in physiology. He has held the posts of Oliver Sharpey lecturer at the Royal College of Physicians, University Reader in Physiology, and Fullerian Professor of Physiology at the Royal Institution.

UNIVERSITY OF LONDON.—At a meeting of the Senate held recently, Prof. E. A. Gardner, Vice-Chancellor, being in the chair, it was announced that Prof. A. V. Hill, F.R.S., has, on his appointment by the Royal Society to a Foulerton Chair, resigned the Jodrell Chair of Physiology tenable at University College. He will carry out his research work at University College, and the Senate have resolved that he shall continue to hold the title of Professor of Physiology in the University of London in respect of the functions to be discharged by him at that College.

The following Doctorates have been conferred:—

D.Sc. in Embryology: Mr. A. S. Rau, an internal student, of University College, for a thesis entitled Contributions to Our Knowledge of the Structure of the Placenta of Mustelidæ, Ursidæ, and Sciuridæ.

D.Sc. in Physics: Mr. W. B. Haines, an internal student, of University College and the Rothamsted Experimental Station, for a thesis entitled Studies in the Physical Properties of Soils.

Dr. W. E. Gye was awarded the William Julius Mickle Fellowship for 1926 in respect of the work which he has carried out during the past five years.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—As the result of the Primary Examination for the Fellowship held from Dec. 8th to 17th, for which 130 candidates presented themselves, 40 were approved and 90 were rejected. The following are the names and schools of the successful candidates:—

J. C. B. Allen, Sydney and Middlesex; H. G. Armstrong, Toronto and Middlesex; N. Asherson, Middlesex and Univ. Coll.; M. R. Barrett, Cambridge and St. Thomas's; Geraldine M. Barry, Univ. Coll. and Royal Free; H. O. Blauvelt, Dalhousie and Univ. Coll.; D. H. Brinton, Oxford and St. Mary's; R. C. Brown, Durham and St. Mary's; A. J. W. Chamings, Cambridge and Middlesex; A. E. De Chazal, Univ. Coll. and Middlesex; A. S. El-Katib, Cairo and Middlesex; J. St. C. Elkington, Cambridge and St. Thomas's; E. S. Evans, St. Bart.'s; I. J. Fraser, Belfast and Middlesex; C. R. E. Freezer and G. F. Gibberd, Guy's; J. Gore, Birmingham and Middlesex; G. M. Gray, Aberdeen and Middlesex; E. V. Greeves, Belfast; G. J. Griffiths, Middlesex; S. J. H. Griffiths, Bristol and London; K. H. Hadley, Melbourne and Middlesex; C. W. Harris, Toronto and Middlesex; A. L. P. Jeffery, St. Thomas's;

R. W. Kenney, Dalhousie and Middlesex; D. McKelvey, Edinburgh and St. Mary's; J. D. McLaggan, Aberdeen and Middlesex; I. McPherson, Middlesex; T. J. Millin, Dublin; M. F. Nicholls, Cambridge and St. George's; A. B. Nutt, Sheffield and Middlesex; T. V. Pearce, St. Thomas's; S. R. C. Price, King's Coll.; R. W. Reid, St. Thomas's; M. Rothkopf, Middlesex; H. H. Stewart and G. S. Storrs, Cambridge and St. Thomas's; A. J. Watson, Middlesex; A. S. Wesson, Univ. Coll.; and W. J. Wilkin, Cambridge and St. Bart.'s.

University of Sheffield.—At examinations recently held the following candidates were successful:—

Final M.B., Ch.B. Examination.

Marjorie T. Crookes, Richard L. Flint, Thomas H. Harrison, John L. Jago, Phyllis A. Moore, and Elisabeth S. M. Sykes.

University of Manchester.—At examinations held recently the following candidates were successful in the subjects indicated:—

Final M.B. and Ch.B. Examination.

R. L. Holt (first-class honours, distinction in Medicine and in Forensic Medicine), Louise Aronovich, H. K. Ashworth, Marion L. Bainbridge, C. H. Bamford, A. R. Barber, J. R. Beal, Agnes M. Bodoano, Frances H. Bowden, John Crook, L. F. Evans, S. J. Firth, Beatrice N. Fletcher, J. B. Fulton, Riad Girgis, T. S. Hanlin, Barnett Hirsh, J. T. C. Keddie, Annie T. Leigh, Annie E. Mackintosh, W. D. Mitton, R. J. Owen, R. M. Pearce, Francis Reynolds, Raphael Shaffer, Agnes G. Smiley, Graham Stenhouse, J. K. Thomas, and J. C. Wilson.

Forensic Medicine.—Marguerite E. Cliff, I. H. Freedlander, John Hunt, Harry Pigott, W. S. Slater, and Olive de la W. Turner.

Medicine.—I. H. Freedlander.

Hygiene and Preventive Medicine.—Florence M. Blades, F. S. Hawkins, John Hunt, T. J. Kay, Harry Pigott, and Olive de la W. Turner.

Obstetrics and Surgery.—J. K. Anderson, Frank Appleton, H. K. Ashworth, Frances H. Bowden, George Bridge, Marguerite E. Cliff, T. K. Clifford, Joseph Crowther, Alec Fleming, Beatrice N. Fletcher, C. F. Garfit, Zaky Hanna, G. W. Jones, Annie T. Leigh, Annie T. Mackintosh, C. T. Mills, G. S. de W. Moll, Joseph Parness, Richard Pendlebury, L. C. Peringuey, Harry Pigott, Mary I. Prentice, Francis Reynolds, B. R. Sandiford, Kathleen Sheehan (distinction in Obstetrics), Maurice Sheehan, J. K. Thomas, W. C. D. Walmsley, J. T. Whitley, and Florence Whitrow.

Obstetrics.—R. H. Barnes, J. F. Caithness, A. F. C. Davey, Margaret Dyson, G. D. Hithersay, and J. H. Kitson.

Third M.B. and Ch.B. Examination.

Pathology.—S. K. Appleton, Dorothy Arning, Harold Arstall. A. H. Baker, Dorothy M. Bradley, E. H. Brooks, Agnes N, Buckley (with distinction), M. A. Chamberlain, Frank Cort. E. B. Davies, H. V. Crabtree, Ralph Edmondson, Muriel M. Edwards, Amy H. Herbert, I. M. Hughes, J. H. Jones, J. A. Longworth, Jean McD. Marshall, H. E. Martin, J. S. Miller, J. W. Murray, Robert Newton, Stanley Nowell, J. R. Nuttall, R. P. Osborne, H. A. Palmer, G. H. Racklyeft, Norah Regan, Marshall Robinson, Eleanor B. Schill, Lucy Stokoe, C. E. Sykes, Alfred Thomas, Herbert Townley, Joseph Vine, F. F. Waddy, Josephine Walmsley, K. H. Watkins (with distinction), and Raymond Whitehead.

Pharmacology.—Leslie Bold, E. H. Brooks, Mary G. Davies, Kathleen McGowan, J. W. Murray, G. L. Normington, H. A. Palmer, Henry Tickle, Joseph Vine, and Raymond Whitehead.

University of Edinburgh.—At the graduation ceremonial on Dec. 18th the following degrees were conferred:—

Doctor of Medicine.

*George Buchanan, †Andrew J. M. Butter, David D. Dunn, (in absentiâ), John B. Ferguson, †Robert M. Galloway, Henry D. Hayes, *Andrew F. Hewat, Eleanor H. Kelly, †James M'Intyre (in absentiâ), †William F. Mair, John D. Robertson, †John P. Stewart, ‡Philip H. J. Turton, and *Alexander B. Williamson (in absentiâ).

*Awarded gold medal for thesis. † Commended for thesis. ‡ Highly commended for thesis.

Bachelor of Medicine and Bachelor of Surgery.

William G. Annan, Jack Beinashowitz, George Black, Elisabeth Brearley, Janet H. Brown, Charles D. Bruce, Jean K. Burnie, Alexander Cairns, Elizabeth F. Clark, George H. Clement, Donald M'M. Crawford, John W. Crichton, James P. Dunlop, Thomas MacF. Edward, Phyllis M. Edwards, Sadik L. El-Zik, Stanley Ford, Ian B. Georgeson, Jack Greenstein, John N. Hay, Isabelle W. Horsley, Alan W. Howarth, Evelyn B. B. Humphreys, William A. F. Hurst, John S. Ingles, Norman Kerr, Rachel Knox, Hugh MacCallum, Margaret A. Mackenzie, Alastair K. Mackintosh, Benjamin A. Meyer, Robert S. Mitchell, Makiwane C. C. Motebang, Mungo Park, Alexander G. Paton, George F. Saunderson, John A. R. Selby, William D. M. Sim, Hilton T. Smith, William Steel, Marjorie Steven, Donald Stewart, Meta H. Thomson, and Dorothea E. Walpole.

Diploma in Public Health.

Sisir Chandra Chatterjee, John Edgar Haine, John Telfer Smeall.

Royal College of Surgeons of Edinburgh.—At a meeting of the College held on Dec. 15th, Dr. A. Logan Turner, President, in the chair, the 25 successful candidates out of 67 entered, who passed the requisite examinations between Sept. 28th and Oct. 5th, were admitted Fellows:—

Harold E. Alexander, Nathaniel Beattie, Mervyn H. Elliot-Smith, Frederick G. Gibbs, Christian F. Krige, Ian H. McClure, Archibald D. McKenzie, Eric S. McPhail, David M. Mitchell, William B. R. Monteith, William Morrison, Douglas L. Muir, Clarence E. Nelson, Edwin R. Ormerod, David R. Owen, John A. Panton, Douglas W. L. Parker, Arnold Perry, Douglas C. Pigdon, James G. R. Scarff, Ian D. Stronach, Thakurdas Chuharmal Ramchandan, Robert Whillis, Rowland P. Wilson, and Dadabhoy Dinsahw Variava.

University of Durham: Faculty of Medicine. At examinations held recently the following candidate were successful:—

Third Examination for Degrees of Bachelor of Medicine and Bachelor of Surgery.

Materia Medica, Pharmacology, and Pharmacy; Public Health; Medical Jurisprudence; Pathology and Bacteriology.—Harold C. Beck, Thomasina Belt, Thomas S. Blaiklock, Ida M. Dodds, Walter Foskett, William A. Kirkpatrick, Leonard H. Lerman, Jerome A. O'Callaghan, William Stevenson, Alfred T. G. Thomas, Edward C. Vardy, and Thomas Welsh.

The Duchess of York has consented to become President of the South London Hospital for Women, Clapham Common.

Royal Sanitary Institute.—The courses of lectures and demonstrations arranged for next term will begin early in January. The first lecture of the course for sanitary inspectors will be delivered on Jan. 4th by Dr. Charles Porter, and the first lecture of the course for meat and food inspectors will be delivered on Feb. 5th by Mr. J. R. Hayhurst. Further information can be obtained from Mr. E. White Wallis, director and secretary, at the Institute, 90, Buckingham Palace-road, London, S.W. 1.

Fellowship of Medicine and Post-Graduate Medical Association.—A further series of open lectures has been arranged from Jan. to March on general subjects. Dr. Herbert Spencer will give the opening lecture on Abdominal Palpations in Pregnancy (with lantern demonstration) on Thursday, Jan. 21st, at 5 P.M., in the Lecture Hall of the Medical Society of London, 11, Chandos-street, W. From Jan. 11th to 23rd the Prince of Wales's General Hospital will hold an intensive course in general medicine, surgery, and the special departments. The daily lecture at 4.30 P.M. is free to members of the Fellowship of Medicine. During January, beginning on the 4th, a series of lecture-demonstrations on Psychological Medicine has been arranged for Tuesdays and Saturdays, at 11 A.M., at the Bethlem Royal Hospital. Also beginning on Jan. 4th a four weeks' course of lectures and demonstrations in the Diagnosis of Nervous Diseases will take place at 5 P.M. at the West End Hospital. At the North-Eastern Hospital a three weeks' course in Infectious Fevers will be given on Wednesdays, at 2.30 P.M., and Saturdays, at 11 A.M., from Jan. 11th to 30th. An all day course has been arranged in Diseases of Children at the Queen's Hospital from Jan. 18th to 30th. Another whole day course will take place from Jan. 18th to 30th at the National Hospital for Diseases of the Heart. From Jan. 11th onwards it is intended to hold special weekly demonstrations in clinical surgery. The first of these will be given at 5 P.M. at St. Mark's Hospital by Mr. J. P. Lockhart-Mummery, and subsequent announcements will appear in the Medical Diary. A copy of each syllabus of the foregoing courses and of the Fellowship General Course programme may be obtained on application to the secretary at 1, Wimpole-street, London, W. 1.

Royal Institution of Great Britain.—The one hundredth course of Christmas lectures adapted to a juvenile auditory will be delivered at 3 P.M. on Dec. 29th and 31st, and Jan. 2nd, 5th, 7th, and 9th, by Sir William Bragg, F.R.S. The title of the lectures is Old Trades and New Knowledge, and the individual lectures deal with the following trades: (1) the trade of the sailor; (2) of the smith; (3) of the weaver; (4) of the dyer; (5) of the potter; (6) of the miner.—The first Friday evening discourse in 1926 will be held at 9 P.M. on Jan. 22nd, when Sir William Bragg will speak on the Work of the Davy Faraday Research Laboratory. On the 29th Sir William B. Hardy, F.R.S., will speak on Films.—Among the general courses of lectures to be delivered before Easter, 1926, is one on Jan. 19th and 26th, at 5.15 P.M., on X Rays and Living Matter, by Prof. J. A. Crowther. Dr. Eric K. Rideal will lecture on Surface Action at 5.15 P.M. on Feb. 2nd and 9th. Prof. Joseph Barcroft, F.R.S., will lecture at 5.15 P.M. on Feb. 16th, 23rd, March 2nd and 8th on the Egg—(1) introductory, (2) the shell, (3) the yolk, and (4) the white. On March 16th and 23rd, at 5.15 P.M., Prof. Cecil H. Desch, F.R.S., will lecture on the Growth of Crystals. Prof. Charles J. Patten will give two lectures at 5.15 P.M. on Jan. 21st and 28th, one entitled the Language of Birds, and the second the Breeding Factor in Birds. Further information may be obtained from the secretary at the Royal Institution, Albemarle-street, London, W. 1.

POPLAR HOSPITAL FOR ACCIDENTS.—At the festival dinner last week Sir Alan Anderson stated that during the past year the hospital had broken records in annual subscriptions, donations, and out-patients' attendances, while the dinner collection, £13,600, was the largest that had ever been known.

APPROVED INSURANCE FUNDS AND MANCHESTER CANCER APPEAL.—At a meeting of the National Union of Trade Union Approved Societies, it was stated that having regard to the occurrence of cancer of the scrotum in the spinning room, the executive of the Operative Cotton Spinners' Association desired to contribute to the appeal recently made. An application was made to the Ministry of Health regarding a proposed gift of £1000 to the Cancer Fund from the approved insurance funds. The Ministry replied that such a gift could not be made under Section 26, because the Manchester Cancer Research Committee was not a charitable institution.

Appointments.

CUMMING, W. M., M.B., Ch.B. St. And., D.P.H., has been appointed Senior Assistant Medical Officer, Grove Park Hospital for Tuberculosis.

LITTLE, C. E., M.B., Ch.B. St. And., to be Certifying Surgeon under the Factory and Workshop Acts for the Rhyl District of the County of Flint.

Vacancies.

For further information refer to the advertisement columns.

Ascot, Heatherwood Hospital.—Res. Asst. M.O. £300.

Bedford County Hospital.—Asst. H.S. At rate of £130.

East Sussex County Mental Hospital, Hellingly, Sussex.—Pathologist. £500.

Hospital for Sick Children, Great Ormond-street, W.C.—Res. Med. Supt. £300.

Ipswich, East Suffolk and Ipswich Hospital.—H.P. and H.S.'s. Each at rate of £100.

Keighley, Victoria Hospital.—Res. M.O. At rate of £180.

Leeds Public Dispensary.—Jun. Res. M.O. £150.

London Lock Hospital, 283, Harrow-road, W., and 91, Dean-street, W.—Hon. P.

London Temperance Hospital, Hampstead-road, N.W.—Cas. O. At rate of £120.

Manchester, Ancoats Hospital.—Visiting Dental S.

Manchester City Education Committee.—Asst. Sch. M.O. £600.

Manchester Hospital for Consumption, &c.—Res. M.O. £200.

Maudsley Hospital, Denmark Hill, S.E.—Deputy Med. Supt. £850.

Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Radiologist.

Plymouth, Didworthy Sanatorium, South Brent.—Res. M.O. £600.

Royal Free Hospital, Gray's Inn-road, W.C.—Second H.P.

St. Mark's Hospital for Cancer, Fistula, &c., City-road, E.C.—Radiologist. £25.

St. Mary's Hospital, Institute of Pathology and Research, Paddington, W.—Research Studentship. At rate of £200.

St. Mary's Hospital, W.—Asst. M.O. in charge of X Ray Dept.

Salisbury General Infirmary.—H.S. £150.

Southport Convalescent Hospital and Sea-Bathing Infirmary.—Res. Med. Supt. £600.

West London Hosp., Hammersmith-rd., W.—Hon. Obstet. Reg.

Wolverhampton and Staffordshire Hospital.—Res. Surg. O. £250.

Births, Marriages, and Deaths.

BIRTHS.

ANDREW BIRD.—On Nov. 22nd, at Lumeah, 101 Kitano-cho, 2-Chome, Kobe, Japan, the wife of Dr. G. Andrew Bird—a daughter.

BAILEY.—On Dec. 13th, at Denburgh Park, Banstead, the wife of R. J. Bailey, L.D.S., of a son.

MARRIAGES.

DUNLOP—HEATH.—On Dec. 14th, at Old Greyfriars, Edinburgh, Gavin Alexander Dunlop, M.B., Ch.B., to Rosamond, daughter of Mr. and Mrs. Heath, Hanworth, Middlesex.

TUNBRIDGE—RODDY.—On Dec. 15th, at Holy Trinity Church, Leamington Spa, William Stephen Tunbridge, M.A., M.B., B.Ch. Oxf., to Mildred Emma Leathes, the younger daughter of Colonel Roddy, C.B., and Mrs. Roddy, of Bareilly, Leamington.

DEATHS.

McILROY.—On Dec. 16th, at The Priory, Roehampton, John Morrison McIlroy, M.R.C.S., L.R.C.P., in his 65th year.

POWELL.—On Dec. 15th, at Cleveland-square, W., Sir Richard Douglas Powell, Bart., K.C.V.O., M.D., aged 83.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

AN ALPINE THERMAL STATION.

BY T. N. KELYNACK, M.D. MANCH., M.R.C.P. LOND.,

SENIOR PHYSICIAN TO MOUNT VERNON HOSPITAL.

LOECHE-LES-BAINS, Leukerbad—or simply Baden as it is known locally—occupies a unique position among European thermal stations. Its natural hot springs are in character and therapeutic properties similar to the famous waters of Bath.

Situation and History.

Leukerbad, with a normal population of 600 souls, is situated in the Canton of Valais in the picturesque valley of the Dala at an altitude of 4630 feet, just below the impressive Gemmi Pass, surrounded by green flower-laden pastures, high alps on which cattle graze, and mules climb in summer, dense forests of pines, sparkling glaciers, and snow fields with rocky peaks from which unrivalled panoramas of the snow-clad mountains of the Bernese Oberland and the giants which lie to the south of the Rhone can be obtained. The village, tucked away as it is on the north side of the Rhone Valley, can yet be readily reached. The Simplon Express from Calais passes through Leuk from whence a narrow-gauge electric and rack-and-pinion railway bringing the traveller direct to the baths of Leuk in an hour. There is a good road 17 km. long up the valley suitable for skilled motorists.

Loeche-les-Bains with the rocky wall of the Gemmi behind.

Leukerbad, there is reason to believe, was known to the ancient Gauls and, like our own Bath, was discovered by the Romans. It is thought that in the first centuries Christian sick folk resorted to the hot springs, but it was probably not until the end of the fifteenth century that the fame of the waters extended to other countries. By 1500 the bathing establishments had developed into important and valuable properties.

The Thermal Springs.

The natural hot springs known to exist are over a score in number; of these the most important are now associated with five hydrotherapeutic establishments, giving systematic courses of baths. Each of the principal baths is connected by covered ways with one or more of the chief hotels, so that the patient can pass directly from his own room to the hot waters. The principal hotels and baths are under one control. The season extends from early in May to the beginning of October, and during recent years endeavours have been made to develop the place as a winter sports station with a season extending from Dec. 15th to the end of February.

The temperature of the water varies from 102° to 124° F. It is conjectured that the depth of the springs is at least 5000 feet, but the conditions which give rise to thermal springs of such constancy are not exactly known. The water is clear and almost tasteless. Chemical analysis shows the presence of sulphates of calcium, magnesium, sodium, and strontium; carbonates of calcium, magnesium, manganese, and iron; chlorides of potassium, sodium, ammonium, and lithium; with traces of alum, silica, arsenic, carbonate of copper, and sulphate of barium. Recent investigation has shown that the waters have radio-active properties.

Bathing Régime.

Patients entering on a course of hydrotherapeutic treatment are expected to consult one of the two doctors in residence during the summer—Dr. A. Bayard and Dr. R.

Zen-Ruffinen—with a view to direction regarding the form, application, and duration of the baths with such other treatment as may be desirable. A full course of baths extends usually over three weeks. The baths are open from 5–12 A.M. Patients generally take their petit déjeuner (coffee and milk, fresh rolls and butter, and conserves) at 7 A.M. while in the bath, served on a tray placed on wooden floats. In addition to the public baths there are family and private baths for individuals. Patients remain in the baths for periods up to several hours, afterwards resting for some considerable time in their own rooms. Thus, in the majority of cases the whole morning, up to déjeuner at 12.30, is devoted to treatment. Along one side of the Grand Bain, connected with the Maison Blanche, is a gallery to which spectators on removing their hats are admitted and who are expected to drink of the waters and contribute a trifle pour les pauvres. At each of the baths are experienced attendants who carry out special forms of hydrotherapeutic treatment and massage. In addition to the baths patients drink the waters and have their rest and exercise regulated. The dietary varies considerably according to the hotel chosen. In addition to the larger hotels and hydropathic establishments, there are a number of inns frequented by tourists.

Indications.

Among the diseases for which the baths at Leuk have proved beneficial are various forms of chronic inflammatory affection, rheumatoid and other arthritis, gout, lumbago, fibrositis, sciatica, and other neuritic conditions; varicose veins, phlebitis, and chronic ulceration of the lower extremities; catarrhal states involving the mucous membranes of respiratory and urogenital tracts; certain skin diseases and renal affections; neurasthenia and convalescence from various acute diseases. For overworked, brain-fagged men and women a course of treatment in this restful mountain station with its invigorating air is often of benefit.

There is a public bath hospital with which is associated, in a separate building, a series of baths. Residence in the hospital, which is under the care of Catholic sisters, and treatment in the baths is available at low fees for suitable necessitous cases from all countries.

On the north side of the village, close to the main road which descends to the Rhone Valley, is an open spring where hot water bubbles up. Simple wooden benches have been erected over the water, and at this spring, open to all comers free of any charge, are to be seen children and village folk side by side with men and women of all sorts and conditions. Partial immersion in this spring produces marked local reaction and is quickly followed by a general reaction. Immersion of feet and legs in the hot spring after a mountain excursion brings about a sense of warmth and comfort. I noticed an old lady with marked arthritis of the knee-joint spreading over the swollen part some of the fine alluvial deposit to form a kind of radio-active paste.

Amenities and Access.

For the young and vigorous there are numberless charming walks and climbs, while for the delicate and elderly there are many and varied walks on easy gradients. There is a Roman Catholic parish church, a Protestant chapel at which services are held in English and French, a chemist and shops in which all the requirements of the visitor can be met. Guides and porters with mules can be obtained by those desiring excursions in the high mountains.

Loeche-les-Bains is a favourite resort with Swiss doctors, and the thermo-mineral springs at this picturesque mountain health station might be better known by British practitioners. The manifold forms of rheumatism, osteo-arthritis, fibrosis, neuritis, and allied affections would reap benefit by a holiday at Loeche-les-Bains and a course of its wonderful thermal baths. Mr. Wattelet, director of the Société des Hôtels at Loeche-les-Bains, will furnish English doctors with full particulars regarding the baths and hotel facilities. A return ticket from London to Loeche-les-Bains costs first-class from £10 9*s.* 5*d.* to £8 18*s.*, second-class, £7 11*s.* 8*d.* to £6 6*s.* 7*d.*, according to route. Full particulars regarding travel can be obtained from the various travel agents or from the London office of the Swiss Federal Railway, 11B, Regent-street, S.W. 1.

THE NEW HEALTH SOCIETY.

A NEW Health Society, or rather "The New Health Society," of which Sir W. Arbuthnot Lane is president, was launched on Dec. 11th at a luncheon given by the Aldwych Club, whose president, Alderman Sir Charles Wakefield, was in the chair. Lord Oxford and Asquith said the aim of the society was not so much to cure the ill as to keep the people well. In England and Wales £12,000,000 were spent annually on sickness and disability benefits for illness that might be prevented. Many diseases were due to artificial methods of our civilisation, and in particular to diet; 80 per cent. of the most disabling forms of illness were due not to malnutrition, but to wrong feeding, too much meat, too little milk. The society would work with the family doctor and the specialists. Its main business was to disseminate knowledge of the laws of health and the causes of disease. New methods had reduced the prison population, new methods would, he hoped, lessen the strain on the voluntary hospitals. Mr. Philip Snowden said that we lost in industry, from physical weakness, £400,000,000 worth of work every year. To advise more milk was good, but to provide more milk for the children was more important. He hoped that the alcohol question and waste therefrom would not be forgotten. Subscriptions were asked for, and £525 at once given.

On the evening of Dec. 12th Lady Oxford and Asquith broadcasted an appeal from London on behalf of the new society. She had just read how Queen Elizabeth got herself a bathroom, in which she expected to be able to have a bath every three months, whether she needed it or not. That was in the bad old days, as they should be called, when medicine was superstition mainly, when people believed in witchcraft, and no one knew how to get rid of diseases like plague, rampant everywhere. Our present outlook was wide, hospitals were nearly perfect, and our great hope was in prevention, and we wanted all to be fit. But not everyone knew how to keep fit; it was part of the work of this society to show them. It would bring benefits to large employers of labour, whose staffs are reduced by illness, to mothers whose children it would save. It would, Lady Asquith concluded, help the doctors, and would financially benefit the country as much as 2*s.* off the income-tax.

A STOLEN CAR.

To the Editor of THE LANCET.

SIR,—My car was stolen yesterday by the following *modus operandi.* One confederate stands by the surgery door whilst the other hides on the remote side of the car, and, if disturbed, the former says, "Will you come round to Mrs. Collins—a midwifery case—*not* at once, but after surgery will do." And whilst the doctor is investigating the particulars (which were lies) the confederate starts the car and they go off together. Will anybody assist in detaining this man if he calls with such a cock-and-bull story.—I am, Sir, yours faithfully,

R. LARKIN, M.D.

Trinity-sq., Southwark, S.E., Dec. 16th.

*** We are glad to learn that Dr. Rance Johnson of Hampstead, whose car was stolen while he was seeing a patient in Bedford-square on Dec. 17th, has recovered it through the police, albeit in damaged condition. Dr. Johnson suggests that companies insuring motor-cars for medical men should insert a special clause in the agreement making an allowance for hire during the temporary loss of a car from accident or theft.—ED. L.

CALENDARS AND DIARIES FOR 1926.

A CONVENIENT block calendar for 1926 (The A.F.D. Diary) has been issued by the Anglo-French Drug Co. (238A, Gray's Inn-road, London, W.C.1). There is provided for each day throughout the year a sheet of white paper, 4 inches square, for written memoranda, and the stiff hinged cover provided preserves the privacy of the notes and lends the calendar the appearance of a bound book. A certain number are available gratis to medical men on application to the company.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED DEC. 12TH, 1925.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 144 (previous weeks 115 and 105); scarlet fever, 1962; diphtheria, 986; enteric fever, 37; pneumonia, 1917 (previous weeks 1176, 1531, 1186, and 889); puerperal fever, 63; cerebro-spinal fever, 10; acute poliomyelitis, 10; acute polio-encephalitis, 1; encephalitis lethargica, 44; dysentery, 9; ophthalmia neonatorum, 112. There were no cases of cholera, plague, or typhus notified during the week.

The cases of small-pox were reported from the following counties: Derby, 21 (Derby C.B. 6, Bolsover 2, Blackwell R.D. 13); Durham, 87 (Gateshead C.B. 2, South Shields C.B. 1, Sunderland C.B. 1, Blaydon 52, Ryton 2, Seaham Harbour 1, Stanhope 2, Whickham 4, Chester-le-Street R.D. 3, Easington R.D. 3, Houghton-le-Spring R.D. 6, Lanchester R.D. 5, Sunderland R.D. 5); Northumberland, 5 (Newcastle-upon-Tyne C.B. 4, Castle Ward R.D. 1); Nottingham, 16 (Nottingham C.B. 3, Hucknall 2, Mansfield 1, Sutton-in-Ashfield 7, Southwell R.D. 3); Yorks, East Riding, 6 (Kingston-upon-Hull C.B.); Yorks, West Riding, 9 (Rotherham C.B. 1, Sheffield C.B. 2, Hipperholme 1, Rawmarsh 4, Halifax R.D. 1).

Deaths.—In the aggregate of great towns including London, there were 7 deaths from enteric fever (London 4), 71 from measles, 17 from scarlet fever, 44 from whooping-cough, 38 from diphtheria, 116 from influenza (previous weeks 100, 73, 61, and 44). In London itself there were 21 deaths from measles, 12 from diphtheria, and 22 from influenza.

KROPP

Tales of Kroppman

LUCK and Judgment—Some fellows say that a good razor is just a matter of luck. So it is if it's a KROPP. It's a matter of VERY GOOD luck and a matter of VERY GOOD judgment too.

When you buy a KROPP your luck's well in, and as for judgment, your wisdom would have Solomon guessing right into the night. So—if you're wise—Buy a Kropp for Contentment.

In case, black handle, 10/6; ivory handle, 18/-
From all hairdressers, cutlers, stores, etc.

Wholesale only: **OSBORNE GARRETT & CO., LTD., LONDON, W. 1**

A Jaeger Specialty.

"TWO-FOLD" UNDERWEAR.

This special Underwear is made of two layers of Stockinet ingeniously joined together so as to form one fabric. The air between the layers acts as a slow conductor of heat, and less heavy garments are required, therefore, than is the case with a single fabric.

The inside is so smooth that the possibility of irritation is reduced to a minimum.

JAEGER
Pure Wool

TWO-FOLD UNDERWEAR

We shall be pleased to send a pattern of the "Twofold" fabric and a Catalogue if you will kindly apply to

A High Quality Saloon at Moderate Cost.

One day it rains; another, it snows; and next, perhaps, it blows.

WHATEVER the weather you will be snug and comfortable in a "Standard" Pall Mall Saloon. It is an attractive closed car at moderate cost; economical to run and in every way reliable. Plenty of room for four or five people.

The design of the bodywork has been vastly improved and four wheel brakes are fitted. Extensive additions have been made to the equipment, which now includes shock absorbers and spring gaiters, clock, 2 dash lamps, ash tray, driving mirror, scuttle ventilator, &c.

Pulling better than ever, after 15,600 miles

"My Austin Twelve has now done 15,600 miles in less than twelve months . . . To-day, after this mileage, she is pulling better than ever, and beyond decarbonising, etc., the engine has not been touched . . . From Monday morning to Saturday noon she gets no attention whatever . . . If anyone is seeking a thoroughly reliable and economical car, I can honestly recommend the Austin Twelve."

AUSTIN TWELVE from **£340**

The above extracts from a letter from A. E. W., a Bradford Austin owner, are convincing tribute to just those qualities the doctor deems essential—perfect efficiency and reliability with a minimum of attention; durable quality; economy in service. Write for the complete Austin Catalogue to-day.

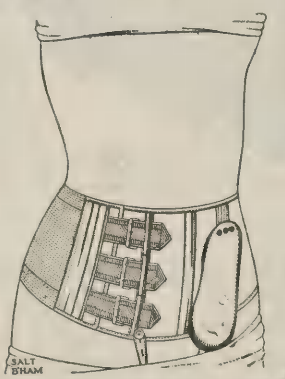
Surgical Service-Specialised!

SALT'S PATENT COLOSTOMY BELT.



ADVANTAGES:
1. Sterilizable.
2. Absence of Odour.
3. Accessibility of removal.

No. 1.
Easily Sterilized.

The receiver (which is detachable from the belt) is moulded of specially vulcanised rubber which is sterilizable by boiling. This rubber portion will last considerably longer than those made of ordinary rubber and celluloid.

Medical Men are invited to apply for our special Colostomy Leaflet which gives fullest details and embodies special order form.

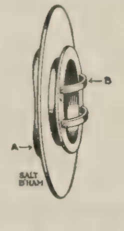


Fig. 1. Shows the moulded rubber cup (which may be boiled). The pad is indicated by "A" and rim (which when in position is *outside* belt), is shown at "B," which holds the mouth of the indiarubber bag.

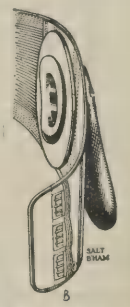

Fig. 2. Illustrates the method of attaching cup and bag to belt. The pad lies next to the body and the bag to receive fæces is stretched over the rim of cup *outside* the belt.

COPYRIGHT

Kodak X-Ray Reduction Camera

for Bromide paper prints, film transparencies or lantern plates

With the new Kodak X-Ray Reduction Camera no focussing is required—automatic focussing scales are fitted to ensure that the reductions are always critically sharp. The Camera simplifies the system of reducing "Dupli-Tized" Film negatives of all sizes up to 17 × 14—to lantern slides or Bromide prints of 6¼ × 4¾ or smaller.

The Negative Illuminator 17 × 14ins. fitted with lampholder, 200 watt Lamp, 10 feet of electric flex and wall plug, detachable hinged film negative frame, double glazed, set of 8 masks, and brass wire frame hinged on illuminator and draped with black material to eliminate reflection.

The Camera is fitted with Kodak Anastigmat Lens f7·7 and Ball Bearing Shutter and is attached to skeleton platform support to ensure accurate centration.

One double plate-holder is included in the complete outfit with two ½ plate sheaths for film or Bromide paper and two lantern plate carriers.

Price complete £21

Write for full particulars.

For Invalids and Convalescents

Horlick's Malted Milk presents the Proteids and Carbo-hydrates of Cereals and Milk in the proper ratio which affords a maximum of nutrition with a minimum tax on digestive effort. It materially assists the building-up processes by making good the wastage entailed by illness, accelerates the recuperation of the digestive and assimilative powers, thereby preparing the way to a resumption of a solid diet Complete in itself and ready in a moment by briskly stirring the powder in hot or cold water only.

Liberal samples free to Members of the Profession.

BISMOLAN

For the Treatment of Hemorrhoids

1. Lubricate the rectal region prior to defecation, to protect the hemorrhoids from injury and infection.
2. Introduce an easily soluble suppository, to bring about deturgence and contraction of the rectal mucosa and the blood vessels.

These objects are effectively accomplished by BISMOLAN Preparations — BISMOLAN SUPPOSITORIES and BISMOLAN OINTMENT—which contain bismuth-oxychloride, eucain, menthol and suprarenin.

BISMOLAN Preparations are antiseptic, prevent the passage of infectious germs into the veins, contract the mucosa and blood vessels, cause the hemorrhoids to diminish in size, thereby avoiding the danger of bleeding.

Dioxogen

(Trade H_2O_2 12V Mark)

The standard of quality for Hydrogen Peroxide.

UNEQUALLED FOR STABILITY.

A potent yet harmless antiseptic and disinfectant for internal and external use.

"Dioxogen" may be used with assurance as to its activity and freedom from preservatives and impurities.

"Dioxogen" has the following points of merit which distinguish it from other makes of Hydrogen Peroxide:

Purity and very low acid content.
Strength 25% higher than B.P. standard.
Remarkable stability and keeping properties.

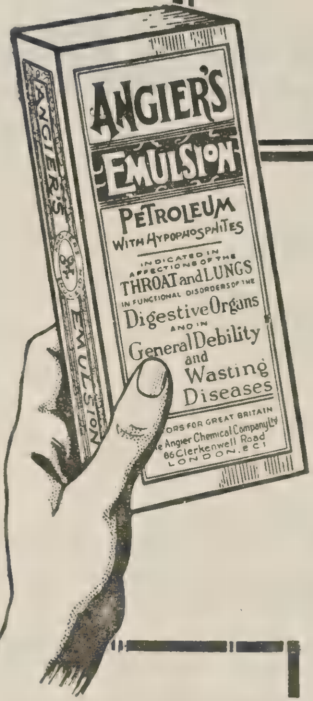
EMULSION OF
PETROLEUM



FREE
SAMPLES TO
THE MEDICAL
PROFESSION

ANGIER CHEMICAL Co., LTD.,
86 CLERKENWELL ROAD,
LONDON, E.C.1.

Angier's Emulsion is made with petroleum specially purified for internal use. It is the original petroleum emulsion—the result of many years of careful research and experiment.

In Gastro-Intestinal Disorders of a catarrhal, ulcerative, or tubercular nature, Angier's Emulsion is particularly useful. The minutely divided globules of petroleum reach the intestines unchanged, and mingle freely with intestinal contents. Fermentation is inhibited, irritation and inflammation of the intestinal mucosa rapidly reduced, and elimination of toxic material greatly facilitated. An improved state of the digestive functions and modification of the various symptoms traceable to auto-intoxication are notable results.

During Convalescence. After fever, dysentery, operations, or after any serious illness, Angier's Emulsion will improve and strengthen the organs of digestion and assimilation, and enable patients to derive the fullest benefit from any prescribed diet. The creation of appetite and the return of normal digestion is quickly brought about by its regular use.

Frail, Nervous Patients respond actively to Angier's Emulsion. It is a tonic in effect and an aid to digestion. Being a perfect Emulsion, it is presented in a form pleasing to the taste and acceptable to the most fastidious. Its good effects are accomplished in a safe and natural manner without entailing any extra work upon the weak or overburdened system.

ANGIER'S EMULSION

THE ORIGINAL & STANDARD EMULSION OF PETROLEUM

OF IMPORTANCE
TO
MEDICAL MEN

SINCE the introduction of LYSOL nearly thirty years ago it was always guaranteed by the Original Makers to contain 50% of free cresols. Upon this percentage of free cresol was based its bactericidal powers.

DIRECTIONS for the use of LYSOL in the disinfection of fæces, the cleansing and disinfection of the skin before operations, the sterilising of instruments, etc., etc., which have been followed for a great number of years, were compiled only after exhaustive bacteriological tests.

FROM these tests it is certain that LYSOL in the given dilutions will perform the work expected from it, and in so far as the Original LYSOL is concerned certainly will do so.

ATTENTION, however, is drawn to the fact that there is now being sold as " LYSOL " preparations which contain less than 3% cresol, and it follows that should such preparations be used in the strength of dilutions indicated in the Original LYSOL that they will be practically useless for the purposes intended.

MEDICAL MEN are therefore asked to use and prescribe MARSHALL'S LYSOL, which is guaranteed to contain full 50% of free cresols, and is made according to the formula (now in our possession) followed by the Original Makers since LYSOL was first offered to the Medical Profession up to the present day.

Samples free to Medical Men.

LYSOL LTD. LONDON S.W.20

Restores Natural Bowel Action

AMONG the many remedies for constipation, bowel torpor, intestinal stasis or any form of dyschezia of functional origin, there is hardly one that has met with such instant approbation and acceptance by discriminating physicians as

AGAROL
BRAND COMPOUND

AGAROL is the original Mineral Oil — Agar-Agar Emulsion, and has these special advantages:

Perfectly homogenized and stable; pleasant taste without artificial flavouring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbances; ***not*** *habit forming.*

Any practitioner needs only to test this scientifically balanced combination of pure mineral oil, agar-agar and phenolphthalein in some severe case of constipation to understand why Agarol is winning the regard and confidence of a constantly increasing number of medical men. He will find that Agarol

1st—*produces* prompt and satisfying bowel evacuations;

2nd—*increases* the bulk, softness and plasticity of the fæcal mass, thus supplying the natural stimulus to peristalsis;

3rd—*imparts* functional tone and power to the intestinal muscles by maintaining conditions within the canal that induce repeated bowel action;

4th—*restores* functional activity of the bowels, so that regular evacuations soon begin to take place naturally, and continue without the need of further medication.

In Agarol, therefore, the practitioner has a remedy that *not only relieves* bowel malfunction *but actually corrects* it. Thus its influence is not temporary but persistent.

A generous supply for clinically testing will be sent to physicians on request.

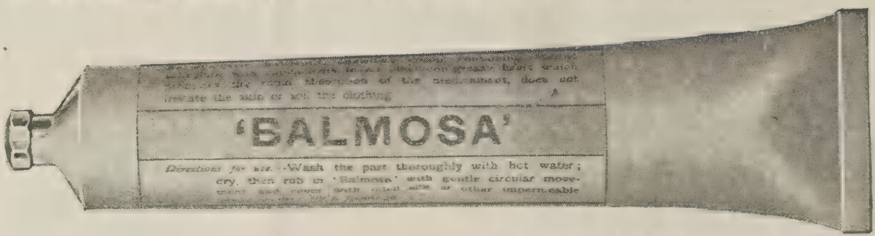
For Acute Rheumatism



ANALGESIC—ANTISEPTIC—NON-IRRITANT

THIS snow-white cream, which contains Methyl Salicylate with rubifacients, has a non-greasy base which forms a good lubricant with exceptional penetrative properties. The greatest authorities on Rheumatism recommend the early application of the Salicylates so as to bring the patient under the influence of the drug as soon as possible. 'Balmosa' is found to be ideal for this purpose and is especially *efficacious in cases where local pain and swelling persist.*

OTHER USEFUL OINTMENTS ARE

'OZOLINE'

A very powerful antiseptic and deodorant with an emollient base. In contact with moisture, 'Ozoline' liberates nascent oxygen, to which its properties are due.

UNG. 'RENAGLANDIN'

which consists of a soothing emollient base into which has been introduced 10% of a 1-1000 solution of 'Renaglandin'—an exhaust of the whole of selected healthy glands.

UNG. 'RENAGLANDIN' ANÆSTHETIC

Where pain or local irritation are pronounced, it is recommended that this variation be used, for example, in Fistula and Hæmorrhoids. Eucaine Lactate is introduced into the Ung. 'Renaglandin,' thus intensifying the analgesic and anæsthetic effect.

O. & S.

Intestinal Stasis and

VIROLAX

the nutrient laxative

Virolax combines the nutrient properties of Virol with the lubricating effects of Medicinal Paraffin.

Though the Virol is used rather as a vehicle for the paraffin than for its food value, yet there are many occasions on which it is a distinct advantage to be able to supply easily digested food with a bowel lubricant.

Paraffin acts not only by directly facilitating the progress of the intestinal contents, but by inhibiting undue bacterial growth. Virol forms an admirable vehicle for the paraffin, which in Virolax is so finely emulsified that it mixes immediately with the intestinal contents and does not give that uneasiness in the lower bowel, often accompanied, in the case of unemulsified paraffin, by leakage of paraffin from the rectum.

Virolax and Intestinal Bacteria

Investigations have shown that Virolax has a peculiar selective action on certain bacteria which are known to be the cause of intestinal toxæmia. This fact goes far to explain the results of the Clinical use of the preparation and demonstrates the superiority of Virolax over liquid paraffin in its pure state.

CYRUS THE GREAT—AT FIRST A PETTY KING AND THEN BUILDER AND RULER OF THE MIGHTIEST EMPIRE DOWN TO HIS TIME.—Cyrus, King of the petty state of Persis within the borders of the Median empire, rebelled against his vassalage to his kinsfolk, the Medes. He succeeded in throwing off the yoke, deposed the king and became head of a Persian empire. This meant hardly more than change of dynasty, for there was little distinction between Medes and Persians; internal administration continued almost undisturbed. He next defeated Crœsus, the fabulously wealthy king of Lydia, and annexed his territory before his allies the Babylonians, Egyptians, Spartans, Phrygians and Ionians could come to his aid, and these also he reduced to submission one after the other. In the East he subdued many tribes and annexed a great part of what is now Afghanistan. In a single campaign he defeated the army of Nabonidus and brought the Neo-Babylonian monarchy to an end; as a consequence, the Babylonian provinces in Syria were brought within the Persian Empire. Cyrus displayed remarkable qualities both as a general and as a man. As king of the then civilised world, he inaugurated an era of more enlightened and humane rule. He was the first great ruler of the Indo-European race in history. The accompanying bas-relief is the oldest identified sculpture of the Achaemenian period.

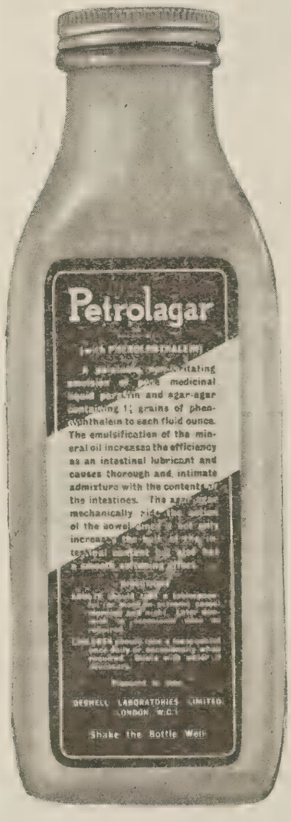
Petrolagar

DESHELL
(TRADE MARK)

A PRINCIPLE EFFECTIVELY APPLIED



It is not the purpose of the Deshell Laboratories Limited to propound a new theory as to the treatment of habitual constipation. The principle of intestinal lubrication is not novel; it has been immortalised by the pronouncements of recognised medical authorities.

It is with the more effective practice of this principle that we are concerned.

We approach the physician purely from the standpoint of the pharmaceutical chemist offering SOMETHING BETTER than the ordinary plain mineral oil supplied for the purpose. Our problem has been to overcome the objection of nausea, leakage, insufficient bulk, unsatisfactory end results. We feel justified in stating that we have accomplished our purpose in PETROLAGAR (Deshell).

In brief, PETROLAGAR (Deshell) presents a palatable non-irritating emulsion of a fully saturated mineral oil with agar-agar. The emulsion admits of more intimate admixture with the fæces, and hence a greater degree of lubrication. The agar adds soft bulk, mechanically aids peristalsis, decreases tendency to leakage, and secures palatability.

PETROLAGAR (Deshell) is now manufactured in LONDON and because of its outstanding point of superiority and ethical presentation to the medical profession merits consideration where intestinal lubrication is desired.

PETROLAGAR is issued in Pound and Half-Pound sizes as follows:—

PETROLAGAR (Plain) No. 1.
PETROLAGAR (Phenolphthalein) No. 2.
PETROLAGAR (Alkaline) No. 3.
PETROLAGAR (Unsweetened, no sugar) No. 4.

Clinical Trial Samples will be sent on request.

"A Perfect Combination of Malt Extract with Cod-Liver Oil"—*B.M.J.*

"Bynol" contains 30% by volume of the highest grade Norwegian Cod-Liver Oil very finely emulsified with the "Allenburys" Malt Extract and aromatics, thus producing a rich, easily digestible and palatable product. The main ingredients, particularly the Cod-Liver Oil, are rich in vitamins which are conserved in their full potency by the special processes used in the manufacture of the product. "Bynol" is of special value to those who require additional fat and vitamins beyond what is supplied by an ordinary dietary—to backward and weakly children, nursing mothers, and those suffering from malnutrition or having a predisposition to phthisis and respiratory diseases in general. The usual dosage is from one teaspoonful to one tablespoonful three times a day after meals.

Issued in wide-mouthed jars containing 10, 20 and 50 fluid ounces.

Clinical trial sample will be sent post free to members of the Medical Profession.

"ICHTHYOL"

(SULPHONATED SCHIST-OIL PREPARATION)

IMPORTANT NOTICE.

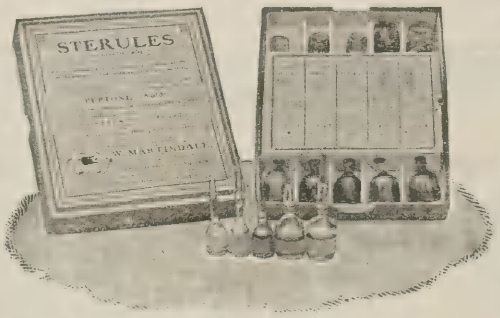
It has been brought to our attention that the rights of our Principals in the Registered Trade Mark, "Ichthyol, are being infringed by purveyors of inferior substitutes and other schist-oil preparations, and we hereby give notice tha it is our intention to preserve by every means our definite right in the trade mark.

The use of the word "Ichthyol" in connection with products other than those of the Ichthyol Co., Cordes, Hermanni and Co., is incorrect and misleading.

There are a number of substitutes and Sulphonated Schist-oil preparations offered, but only the "Ichthyol" of the Ichthyol Co., Cordes, Hermanni and Co., is genuine, and can properly be described by the trade mark. Medical Men are therefore respectfully warned against accepting any other product offered as "Ichthyol," or just as good. The reports which have appeared over a period of forty years in the Medical Press all over the world, revealing the beneficial nature of "Ichthyol" treatment in Dermatology and other branches of medical work, refer to the original genuine "Ichthyol." Formulary and other particulars can be obtained of the sole representatives.

W. DEDERICH, LTD., Stanley House, Dean Stanley Street, Westminster, S.W. I.

If there is any difficulty in obtaining locally supplies of the genuine "ICHTHYOL," please communicate with the above firm direct.



PEPTONE in ASTHMA

The treatment has been applied not only to asthma, but also to such of its congeners as hay fever, associated skin affections, angio-neurotic œdema, cyclic vomiting, periodic diarrhœa, and the migraine-epilepsy syndrome; in short, to such conditions as exhibit an anaphylactic character or sensitisation.

Analytical report states:—"The results show 'DIAMALT' to be a thoroughly satisfactory preparation of the highest degree of excellence."

DIAMALT

WITH

33% COD LIVER OIL

Equivalent to over 40% by measure.

Cod Liver Oil is the most easily assimilable of all fats employed to improve nutrition in wasting diseases. It is estimated to contain about 200 times the amount of fat soluble vitamin present in butter.

In 1-lb., 2-lb., and 4-lb. jars.

THE BRITISH DIAMALT COMPANY, Sawbridgeworth, HERTS.

THIS PREPARATION IS NOW OBTAINABLE IN 5-oz. BOTTLES.

MIST. DAMIANÆ CO. (HEWLETT'S)

MIST. DAMIANÆ CO. (Hewlett's) will be found to possess all the properties of Damiana, viz.:—Its alterative effects on the alimentary canal and tonic action upon the brain and nervous system generally. It is a well-known fact that exhaustion of the organs and tissues, neurasthenia, and premature decay, are far more prevalent at the present day than ever before. The causes are numerous and complex, but, perhaps the principal reason is that multitudes have to toil harder with their brains than any previous race. The resulting cerebral anæmia is, therefore, one of the most general complaints in modern life. Not only is it found amongst the professional literary men, but busy merchants and overworked scholars are equally the subjects of enfeebled nerve power and deficient vitality.

In all these various forms of loss of nerve power Mist. Damianæ Co. (Hewlett's) is a powerful remedy, relieving the exhaustion and conferring renewed capacity for mental and physical endurance.

As a nerve tonic and brain stimulant it is unequalled, and its invigorating properties will be found invaluable in many diseases where there is great depression and exhaustion. In paraplegia, hemiplegia, and partial paralysis, it is particularly indicated, and may be suitably and satisfactorily employed wherever a powerful nerve stimulant and restorative are required.

Dose—One or Two Drachms in Water.

Packed in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. Bottles.

DR. de JONGH'S
LIGHT BROWN COD-LIVER OIL

In prescribing Cod-Liver Oil the Medical Profession can confidently rely upon Dr. de JONGH'S OIL giving the most uniform and satisfactory results. Dr. de Jongh's Light Brown Cod-Liver Oil is prepared from the oils obtained from the livers of fish caught in the region of the Loffoden Isles off the Norwegian coasts. The oils are naturally produced, and no process in their preparation or mixing can conduce to the destruction, either partial or total, of the vitamins which are now recognised as being such an important factor in dietary and a valuable adjunct to medical treatment. The proprietors, Ansar, Harford & Co., Ltd., 182, Gray's Inn Road, London, have always maintained the high quality which the late Dr. de Jongh insisted was essential if the full curative value was to be obtained. It will be found invaluable in the treatment of Diseases of the Throat and Chest, Infantile and all Wasting Diseases.

Sold in Imperial Pints and Half-Pints by all Chemists.

FOR INTERNAL TREATMENT OF GONORRHŒA, URETHRITIS AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT.

Santal Midy Capsules have been prescribed with uniform success for over 30 years. Distilled from carefully selected Mysore Sandal Wood, the oil is bland and remarkably

FREE FROM THE IRRITANT AND NAUSEATING EFFECTS

which are provoked by many preparations.

SANTAL MIDY

There is a marked absence of Gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permit its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-urinary Tract. The capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Générale, 8, Rue Vivienne, Paris, and sold by most Chemists and wholesale Druggists throughout the world.

U.K. Agents: WILCOX, JOZEAU & CO., 15, Gt. St. Andrew St., W.C.2.

The Doctor's Cocoa

The value of **Schweitzer's COCOATINA** has been recognised by the Medical Profession for over **50** years, and its claims have been endorsed by many of the most eminent authorities on dietetics.

SCHWEITZER'S
COCOATINA

COCOATINA, in addition to its high nutritive value, is rich in theobromine, and is, therefore, valuable as a cardiac stimulant for patients after operation.

COCOATINA is an ideal nutrient in cases of gastric and duodenal ulcer. It is easily digested and occasions no irritation.

Hanson's Special Whisky for Invalids

The Lancet says: "There can be no question that this Whisky is thoroughly matured . . . smooth and soft to the palate. The claim that it is relatively free from acidity is correct. In cases in which a stimulant is advisable or allowed by a medical man, the purest and oldest should be employed . . . This Whisky is particularly rich in ethers, the amount being 158 grammes per hectolitre of alcohol. From this standpoint this Whisky should serve for the same medicinal purposes as genuine Old Brandy."

City of Manchester Education COMMITTEE.

APPOINTMENT OF ASSISTANT SCHOOL MEDICAL OFFICER (MAN).

Applications are invited from fully qualified Medical Practitioners for the post of Assistant School Medical Officer.

The person appointed will be required to devote his full time to the duties of the office, and preference will be given to those who have a knowledge of Refraction.

Salary £600 per annum, rising by yearly increments of £25 to a maximum of £750. There is a yearly allowance of £10 for travelling expenses.

The person appointed will be required to contribute to the Superannuation Scheme of the Corporation.

Forms of application may be obtained from the undersigned and should be returned not later than Saturday, 9th January, 1926. SPURLEY HEY, Director of Education.

Education Offices, Deansgate, Manchester,
16th December, 1925.

United Services Fund.

HEATHERWOOD HOSPITAL, ASCOT.

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from fully qualified Medical Practitioners (bachelor) for the above post.

Candidates must have held some appointment in a General Hospital.

The present Hospital accommodation is 136 beds for the treatment of Surgical Tuberculosis and other forms of crippledom.

The appointment will be for a period of twelve months and may be extended at the end of that time.

Remuneration is at the rate of £300 per annum, together with residence, board, and laundry.

The officer appointed will be required to devote the whole of his time to the duties of the office, to give anæsthetics, &c., and generally to act under the supervision and direction of the Medical Superintendent.

Applications, stating (1) age, (2) qualifications, (3) experience and appointments held, accompanied by copies of three recent testimonials, should be forwarded to the Organising Secretary, United Services Fund, 29, Cromwell-road, South Kensington, S.W. 7, before the 8th January, 1926.

Further particulars can be supplied on application to the Medical Superintendent, Heatherwood Hospital, Ascot, Berks.

County Borough of Plymouth.

DIDWORTHY SANATORIUM, SOUTH BRENT.

RESIDENT MEDICAL OFFICER.

Applications are invited from duly qualified and registered Male Medical Practitioners, of at least three years' standing, for the post of RESIDENT MEDICAL OFFICER of the Didworthy Sanatorium (72 beds), South Brent. The gentleman appointed will be required to devote the whole of his time to the service of the Plymouth Corporation, and will be on the staff of the Medical Officer of Health, and must pass an examination by the Medical Officer of Health as to his health. He will undertake such work in the diagnosis, treatment, and prevention of Tuberculosis, and such other duties as the Town Council and the Medical Officer of Health may from time to time direct.

Candidates for the post must not be more than forty years of age, and must have had special experience in the day-to-day supervision of a Sanatorium. A knowledge of work at Tuberculosis Dispensaries will also be considered as an additional qualification, and, other things being equal, preference will be given to candidates who hold a Diploma of Public Health or a Degree in State Medicine.

The salary will be at the rate of £600 per annum, together with furnished residence and washing.

A form of application will not be provided, but candidates should state their ages and whether they are married or single. The appointment will be terminable by three months' notice on either side.

Applications, together with copies of not more than three recent testimonials, should be sent to the Medical Officer of Health at his Office on or before January 6th, 1926.

Canvassing will be a disqualification, but twenty-five copies of the application and testimonials may be forwarded to the Medical Officer of Health, Town Hall, Stonehouse, Plymouth, for the use of the Committee. R. J. FITTALL, Town Clerk.

PRACTICES AND PARTNERSHIPS FOR SALE.

1. SOUTH-WEST OF ENGLAND.—PARTNERSHIP.—In a delightful Residential and Seaside Resort (population 6000 and increasing) the third or Half Share of a good-class, well-established, non-panel, and non-dispensing Practice, averaging about £3000 p.a. Visits 5s. to 21s. Very little Midwifery. Extremely attractive and well-situated house with ample accommodation and garden. Price £3500, part on mortgage. Premium 2 years' purchase.
2. LONDON (NORTH).—In a pleasant Northern Suburb an old-established Mixed-class PRACTICE worth last year £645, including panel of 225. Visits 3s. 6d. to 10s. 6d. Practically no Midwifery (3 cases last year) or night work. Good house (3 reception and 5 bedrooms, &c.) on lease; rent £85. Premium £700.
3. LONDON, S.W.—PARTNERSHIP.—A One-sixth Share is for disposal (owing to the retirement of the senior partner) in an exceptionally sound Middle- and Working-class Practice. Income for the immediate past year over £7000, including a panel of 4000. Fees 2s. 6d. to 7s; Midwifery 3 to 5 guineas—only about 40 cases yearly. Suitable house with garden; rent £90 p.a. Premium for share £2000.
4. RIVIERA.—SEASON PRACTICE.—Well-established entirely good-class Practice, producing over £2000 a year. Fees 1 guinea, and a few at 2 to 10 guineas upwards. No Midwifery. Suitable accommodation available. Introduction for at least one season. Ill-health reason for sale. Premium £4000.
5. WEST MIDLANDS (within 150 miles of London).—In a very pleasant Country Town (population over 5000) in picturesque surroundings, an old-established PRACTICE averaging £2000 p.a., including panel of 1850 and several appointments. Very good house, ample accommodation, and nearly an acre of garden. Will be let at £80 a year or sold for £2000. Premium £3000, £2000 down and balance by instalments.
6. NORFOLK.—Favourite Coast Town.—A ONE-FOURTH, or possibly ONE-THIRD SHARE (with ultimate succession) is offered in an old-established non-panel Practice. Average income £2600, including appointments worth £300. Fees from 3s. 6d. Not much Midwifery. A suitable house can be obtained. Prospects of Surgery, Vendor being on Staff of Hospital. Premium 2 years' purchase.
7. SURREY.—Good Residential District.—Very old-established Mixed General PRACTICE. Average income for the last three years over £2500, including appointments and panel of over 1500. Advice and medicine 3s. to 5s.; visits 5s. to 10s. 6d. Little Midwifery. Good detached house with large garden. Vendor's own freehold. Price £2000, or would be let on a repairing lease. Premium £5300.
8. NEWCASTLE-ON-TYNE AREA.—Old-established Middle- and Working-class PRACTICE. Steady average income of nearly £1400, including panel of 1036. Advice and medicine from 3s. 6d. Midwifery from 2 guineas. About 30 cases. Good corner house, freehold. Price £1800. Premium £1500.
9. SOUTH WALES.—Pleasant Coast Town.—PARTNERSHIP.—A One-third Share in a good-class, non-panel and non-dispensing Practice. Income about £4000, of which £2250 is from good appointments. Fees mainly 7s. 6d. to 21s. Midwifery from 5 guineas—only few cases yearly. Good house in best residential part. Price £1600. Premium 2 years' purchase.
10. SOUTH COAST.—Favourite Town.—PARTNERSHIP.—A One-third Share to commence with in an old-established Middle- and Working-class Practice. Income for the immediate past year about £2100, increasing, and including a panel of 2300. Visits and medicine 3s. to 7s. 6d. Premium 2 years' purchase. Purchaser should be single, preferably not over 30, and a hard worker. Preliminary Assistantship entertained.
11. WORCESTERSHIRE.—Small Country Town.—Very old-established Mixed General PRACTICE, including many county families. Steady average income of over £2000. Panel of 845. Fees from 3s. 6d. to 1½ guineas. Large freehold house, with over an acre of garden. Excellent hunting, fishing, &c. Prem. for practice and house £5000.
12. SOUTHERN SEAPORT TOWN.—PARTNERSHIP.—A One-fifth Share to commence with, in an old-established and very sound Mixed General Practice. Steady average income of over £5000, including good appointments and panel of nearly 3000. Visits from 4s. Premium 2 years' purchase, part by instalments if necessary.
13. SOUTH OF ENGLAND.—Pleasant Coast Town.—PARTNERSHIP. A Share representing not less than £800 p.a. is for disposal in a very old-established Mixed General Practice, held by Vendor 25 years. Panel of 1150. Fees from 5s. Convenient 11-roomed house with garden; rent on lease £110. Premium 2 years' purchase.
14. KENT.—Country PRACTICE.— Within easy access of Coast. Very old-established Mixed General Practice. Income last year £1265, including panel of over 600. Fees 2s. 6d. to 10s. 6d. Very little Midwifery. Good house, standing in its own grounds. Freehold, price £1500. Good sport. Premium £1800.
15. MIDLAND CITY.—Old-established PRACTICE, situated in a populous Industrial centre, and averaging £2462 p.a., including 3200 panel patients. Visits 2s. 6d. and 3s. 6d. Very little Midwifery. Good house available on long lease at £84 p.a., and containing excellent surgery and waiting-room (separate entrance), 2 reception-rooms, 5 bedrooms, &c., large garden and garage. Premium £3400, payable £2200 down and balance by instalments. Unlimited scope.
16. SOUTH-WEST OF ENGLAND.—Coast Town.—PARTNERSHIP.—A recently qualified Graduate (who has held Hospital appointments) can acquire a share representing about £850 to commence with in a non-panel and non-dispensing Practice. Present income about £2750. Fees 3s. 6d. to 21s. Good Hospital and Vendor on the Staff. Premium 2 years' purchase.
17. HANTS.—Old-established Country PRACTICE within 7 miles of a large town. Present income about £700 and increasing. No appointments. Panel of 400. Fees from 5s., with medicine extra. Commodious house, freehold, with ½ an acre of garden. Price £1400. Excellent sport and good society. Premium £1000.
18. LINCS.—Market Town, near Coast.—Old-established Mixed General Practice. Steady average income of £1000, including panel of nearly 800. Visits 3s. 6d. to 7s. 6d., with medicine extra. Car not necessary. Convenient freehold house. Price £1000. Sport of all kinds and good schools. Premium £1200.
19. NEW ZEALAND (NORTH ISLAND).—Unopposed PRACTICE, in very beautiful district on main line, about 36 miles from a large city, and worth about £1300 a year. including an easily worked appointment of £100 p.a. Visits into township 10s., mileage 6s. Midwifery 5 guineas, Good and up-to-date house (built by previous Incumbent), containing surgery, 2 reception, 3 bedrooms, sleeping porch, bathroom, &c., with an acre of ground, tennis-court; rent £120 on lease. Premium £950.
20. ASSISTANT REQUIRED.—Prosperous Midland Town. Outdoor. Salary £400, with rooms, with increase after 12 months, and view to Partnership after 2 years. English or Scotch; age 30–35. Must have some capital available.
21. ASSISTANT REQUIRED.—London S.W.—Chiefly better-class Practice. Outdoor. Salary £365, inclusive. Must be well qualified and experienced. Scotch preferred.

ADVANCE IN TREATMENT of *Hyperchlorhydria and Associated Conditions*

TRADE MARK **ALOCOL** BRAND

Colloidal Hydroxide of Aluminium

Modern medical experience has proven that while the usual alkalis and oxides possess power for neutralizing the normal or abnormal acids of the stomach their action is only symptomatic and transitory. They may give momentary relief to the painful condition, but they also have the effect of aggravating the morbid condition. For this reason they are distinctly contra-indicated, especially in stubborn cases.

"Alocol" does not neutralize acid; it absorbs the excess colloido-chemically and at the same time leaves a sufficiency for normal gastric digestion. The outstanding advantage of "Alocol" as an antacid is that it removes from the system the causative acid radicle (Cl), instead of merely temporarily neutralizing it. "Alocol" can be used for prolonged periods without the slightest harmful effect.

A supply for clinical trial with full descriptive literature sent free on request.

M.198.

"Alocol" is indicated in all conditions in which diagnosis reveals high gastric acidity. It is particularly valuable in the treatment of chronic affections of the stomach, the dyspepsias, especially those of pregnancy, gastric and duodenal ulcer, gastrosuccorrhea and in conditions characterized by gastralgia, pyrosis, flatulence, acid eructation and other symptoms common to gastric disease.
